The harm that comes from flooding large trees, seems to be due to the nature of the tree. In its natural habitat, the weather is favorable to these conditions when such wettings have taken place, but in an arid climate and in very hot weather, it seems to have a deleterious effect on heavy soils.

The Furrow System.

There are many advantages with the furrow system. It is the cheapest and most convenient method of applying water in a grove. When properly managed, as much water can be put into the soil and practically all of it saved, as by the check system.

By making the furrows not less than ten inches deep by running the plow both ways, a ridge is formed on both sides, which can be dragged into the furrows within a few hours after irrigation ceases. This makes a dry mulch on top, which shuts off evaporation almost entirely, at once.

The action of water on different soils is different in each case. In heavy soils the side percolation is greater in proportion to the depth than it is in lighter soils.

This is due to certain principles in physics that we will not discuss here. It is known to be true to the ordinary observer. This being true, it is certain that different distances between the furrows could be profitably made on different kinds of soils, but the practical points must be adhered to rather than following theoretical principles. It is for this reason that nearly uniform methods are employed with the furrow system even where the soils are quite different.

In young orchards with wide variation of soils, different distances between furrows, or put in a different way, a different number of furrows to a space, are wholly practical. When the trees cover a third or half of the space, these considerations are left out because the spaces will not permit.

The Subsoiler.

The subsoiler at one time played an important part in irrigation of citrus trees in heavy soils.

There are perhaps hundreds of orchards which got into such shape that it was impossible to get the water down into the soil deep enough to last from one irrigation to another when in former years, the trees of practically the same size could go for a much longer period.

This was in most cases laid to "plow sole." Some of the most careful observers claim that it was due to the action of irrigation water on certain soils. The trouble disappeared to a certain degree during seasons of moderate rainfall and improved much more after a season of abundant rainfall.

It became a common practice with many growers to run the subsoiler between the rows in the direction of the irrigation furrows. The water would follow in these subterranean grooves and come out at the other end of the grove without wetting the top of the ground between. This pleased some growers for a time, but they soon discovered that the water was not where they wanted it and the trees suffered.

The roots were near the surface and the water was far below and refused to come up in sufficient quantities to supply the wants of the trees. Those who saw the point soon abandoned this method and adopted the deep furrows, and not suffer seriously, but we are told that some groves which were subjected to this treatment a little too long, never have recovered their former vigor and bearing capacity. There is perhaps no method that will ever supplant the deep furrow system for the greatest varieties of soils. Sub-irrigation has proved a failure in every case where it has been tested.

California Horticulturally

By JOHN ISAAC, Sacramento, California

IRRIGATION IN THE SACRAMENTO VALLEY,

IN NO part of the state is more attention being paid to the great problem of irrigation than in the Sacramento valley.

Irrigation Universal.

In the southern San Joaquin, irrigation has long since become a fixed fact, and in Kern, Tulare, Kings and Fresno counties it has been reduced to a science and is depended upon wholly for crops. This is also true, in a less important degree, of the northern counties of the San Joaquin, and here there are some very extensive and important irrigation works; but Sacramento valley has been slow in awakening to the great importance of the work and the wealth which follows in the train of irrigation.

It is true that there has been a great deal done along these lines from the earliest period of the American occupation, and that some great irrigation enterprises have been undertaken, but until a comparatively recent period, this work has been carried on in a desultory and spiritless manner, and some of the greatest irrigation enterprises were strenuously fought by those who would have most benefited by their accomplishment.

But Sacramento valley has awakened to a new era, and there are now under way and projected some of the greatest irrigation works in the state. This has been brought about, too, in spite of the people themselves and has been forced upon them by fate.

The Unirrigated Era.

In the early days of California, when the agricultural succeeded the mining period, it was discovered that grain could be grown on what had been regarded as desert land, and not only grown, but that such land yielded enormous returns and the crops brought big prices.

Those who had gone into wheat growing found themselves getting rich and they added to their domains, until vast areas were absorbed by individual wheat farmers, and the Sacramento valley became one great wheat field.

The small settler was discouraged and driven out, and as the wheat area increased, population decreased. It was this desire to drive out the small settler which prevented irrigation development in the Sacramento valley, and which has kept back this most fertile section of California. But, it is said that time evens all things, and the wheat lords overreached themselves.

Constant cropping, shiftless cultivation and a steady drain on the soil with no returns given thereto, gradually reduced the output; prices for wheat decreased at the same time, and the owner of vast areas of wheat and found himself running behind; his land did not pay.

A Glorious Awakening.

This has led to the cutting up of these great areas into small holdings, and small holdings are not profitable without intense cultivation and for this irrigation is a necessity. Here is the cause of Sacramento's awakening.

We have an enormous stretch of the most fertile land on earth, a climate unsurpassed, soil which will produce anything that grows, and we have seven months of no rainfall. To become profitable, therefore, this land must be irrigated.

With the soil and the climate there is also the water, and the Sacramento valley has the greatest water shed on the Pacific coast, with an abundant supply to irrigate every foot of arable land therein.

The Era of Irrigation.

The Sacramento valley has just commenced its new era of development in this direction and a great incentive to its advancement is being given by the work now being performed by the federal government, which consists of a complete exploration of the entire drainage basin of the Sacramento river for the purpose of locating suitable reservoir sites.

Where such sites have been found their capacities have been determined by surveys and the cost of necessary dams for impounding the water has been estimated. The flow of the various streams running into the valley has been recorded and the amount of water available for irrigating is known to an exactitude.

It is only a question of time, (and with the present influx of population into our state, of a short time) before these reservoirs will be built and canals from them will lead to every foot of available land in the Sacramento valley, which will be watered by the stored up waters of the winter without at all interfering with the navigable river.

Federal Aid to Irrigation.

The building of these reservoirs and the conservation of the winter rainfall will have a doubly beneficial effect on the great valley. At the present time, a very large part of the rainfall in the valley is drained off through its great waterway as soon as it falls.

The river has been shoaled by the constant running into it of the debris from the mines and the natural washings from the mountains for many years past and it is therefore incapable of carrying off the enormous volume of storm water which pours into it from the great watershed which it drains; the result is, destructive floods nearly every year, which destroy infinitely more property than would be the cost of building the dams and checking the flood waters, while at the same time holding them back for use in the season of shortage.

Sacramento valley has altogether too much water at some seasons and not enough at others, and the problem for solution, and which is being rapidly solved, is how to properly distribute it so that it will accomplish all possible good and be prevented from doing great harm as at the present time.

Extent of Reclamation Work.

J. B. Lippincott, Supervising Engineer for the United States Reclamation Service in California, estimates the irrigable land which can be reclaimed by this service at 2,000,000 acres.

It is estimated that many thousands of acres can be irrigated from Puta Creek; 80,000 acres from Cache Creek, and 40,000 acres from Stony Creek. The water from these streams should be used to irrigate the higher valley lands near the points where these streams leave the foothills.

The remainder of the land on the west side of the valley would have to be irrigated by canals taking water from the Sacramento river. There are approximately 1,047,000 acres of land on the west side of the Sacramento valley below Red Bluff, above the overflow line of the flood of 1904.

A Wonderful Transformation.

It is a safe assertion that a great part of the present wealth of the Sacramento valley and a very greater part of its future is, and will be, due to irrigation.

Mining has taken a second place, wheat growing is no longer profitable, while fruit and summer crops are increasing in importance. It is largely upon its fruit and fruit products, upon its raisins and wines that the prosperity of this section will depend, and these will depend for their success upon irrigation.

This will mean more intense cultivation, the cutting up of the large tracts, a denser population, more taxable property, homes for a million more people than there are now in our state and a season of unexampled prosperity.

The Great Value of Irrigation.

The very rapid growth of the irrigated sections of California, their remarkable increase in wealth and population over the non-irrigated sections is a strong argument in favor of the artificial application of water to land.

Several years ago a committee of the United States Senate on the irrigation and reclamation of the arid lands, made a report on this subject in which a comparison was drawn of the growth of the different sections of the state

The state was divided by this committee into groups of counties enriched by irrigation, increasing in irrigation activity, and foothill counties partly irrigated. The former included thirteen counties dependent upon irrigation, and in these the taxable property increased in ten years $248,405,414.

In the second group, "counties increasing in irrigation activity," eleven were named with an increase of $51,544,991.

The third group consisted of eight foothill counties, partially irrigated and showed an increase of $12,657,874. Nearly one-half of the total increase of the value of taxable property of the whole state was made in the thirteen irrigated counties, and the same proportion will hold good at the present time.

It is in Southern California that irrigation has reached its greatest perfection and it is here that we find the greatest prosperity in the state, but the northern portion of the state is rapidly falling in line and it will not be long before it, too, will bourgeon and bear under the magic influence of water applied to the most fertile of soils in the season of greatest growth.

NITRATE DEPOSITS.

There is a generally prevalent idea that it is an admitted fact that the Chilian Nitrate deposits will, at the present rate of working, be exhausted in the near future, probably within about twenty years. This estimate is based upon surveys and calculations made some ten or fifteen years ago, before a complete examination of the pampas outside the province of Tarapaca had been undertaken. In recent years vast deposits have been discovered and surveyed in the districts of Antofagasta, Taltal and Tocopilli, and according to the latest official estimates the store of "caliche" now known to exist and to be workable will suffice to meet all requirements of consumption during the present century.—British Agricultural Press.

Both trees and vines may be "scalded" by allowing water to stand too long in hot weather.

Orchards have been injured by too much irigation, causing the roots to scald.

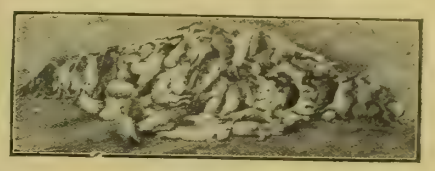
Now is the time to go for gophers with Bille's Gopher Poison. The gophers go for it and it will go for them good and plenty every time.



This is a photo of 201 killed in one day on a ten acre field before they could get back to their holes, with one bottle of

BILLE'S GOPHER POISON

Endorsed by Agricultural Colleges and Experiment Stations. Not one of the ordinary poisons, but in a class by itself. Has had greatest success in the Middle West. The secret being that it is most attractive to gophers, squirrels, etc., and sure death to them. It gives the grain a glossy coating, retaining the poison for weeks. Hundreds also die in their holes by eating it there. We have bought the patent rights for this section and are selling at the eastern price of $1.25 for large bottle. The ingredients cannot be bought at a drug store for that price. Money refunded if not as represented—so printed on the bottle. If your dealer does not keep it send $2.50 for two bottles, express prepaid by us.

We do not send less than 2 bottles.

TO FARMERS AND DAIRYMEN

It will pay every farmer or every farmer's wife to sit right down and write for Sharples "Business Dairying." This valuable book contains information that can be found in no other book, and will help any dairyman to make his business more profitable. It tells How to Feed, What to Feed, How to Care for Feed, What Foods Produce Greatest Amount of Milk, How to Care for the Dairy Cow in the way to get best results, and the whole book is practical. To get all the good out of your milk you should of course use

THE SHARPLES TUBULAR CREAM SEPARATOR

It is not only guaranteed to more than pay for itself annually, but the ease with which you can skim, the low can, the self-oiling bearings, the simple **Tubular** bowl with only one little part inside to wash, the moderate price, are all points you should know about. Send today for the free "Business Dairying" and full information about the Sharples Tubular, giving number of cows you keep. Ask for booklet G. 260

Mrs. J. Renken, Trenton, Ia., says "We cleared $100.00 in six months off seven cows."

Live Stock and Dairy

By Mrs. Minna E. Sherman, Fresno, Cal.

DAIRYING ON IRRIGATED LAND.

THE dairy is a success on irrigated land, for the constantly green feed keeps the cows producing milk steadily. The amount of money made depends today very little on the size of the town supplied, for the difficulty of transporting milk has been overcome by the use of the separator. Cream is a high-priced, concentrated product that can be shipped and arrive in reasonably good condition several hundred miles.

Small Dairies.

The small dairy on forty acres of irrigated land, run by the owner, makes more money per cow than the larger dairy.

The expense of hiring men is saved as well as their carelessness and waste. The children milking the cows are kinder and more watchful. These small dairies are wonderfully profitable when the amount of capital invested is taken into account.

Large Dairies.

The men that run large dairies for money investment usually combine the raising of registered stock with it.

They employ or try to employ a good head man to push the sale of breeding stock as well as the sale of milk and butter.

Success of a Small Dairyman.

On a forty-acre piece of irrigated alfalfa a renter had twenty common cows twenty years ago. He hauled the milk to town himself and served his customers. His wife helped him loyally and as his means increased, the cows increased, and to his credit the wife's labor decreased, until finally she had a pleasant home in town.

A year ago he sold the cows and the milk business. The herd then numbered about one hundred head and had been graded up to almost pure bred Holsteins and Jerseys. The profits from those cows were carefully invested and today an 80-acre orange grove and a 60-acre vineyard are part of his property.

Two children have received a liberal education. A good home has been maintained with more than ordinary comforts of life. Today this man is considered to be worth $150,000, all starting from twenty scrub cows.

Back to the Dairy.

There is no surer way of building up a competence than from a dairy nerd. The money comes in each month, the losses are small, and at any time the cows can be sold for cash.

There are some funny people around in this world. There was an old father that raised a large family of boys on his dairy; when the father died the boys sold the cows and each had a snug little sum of money to start with in some "high-toned" business.

In five years time they were buying cows on time; in five more again sold out to be real estate men; today they came for more cows as they are again broke. Dairying they consider beneath them and yet all the money they or their father ever made was "cow money."

First Alfalfa Butter.

The struggles I underwent twenty-one years ago to make good butter on alfalfa will always be remembered as the first hard work of my lifetime. It was harder than studying Greek, that was mental, this was both mental and physical toil.

Then came the struggle to convince people that the butter was as good as the Coast butter; yet it came in time and the result has been that butter has not been scarce nor has it ever reached the fabulous prices it used to command since the recognition of alfalfa butter.

The Coast butter was made during the flush of grass, then the cows went dry slowly, and the price of butter rose rapidly. The irrigated alfalfa fields now supply green food all the year and the price of butter is more steady.

Old Times.

In the old days in the flush of the spring time the farmers wives made butter everywhere.

It was duly gathered in by the storekeeper, sent to San Francisco and renovated, packed into tubs and shipped to the mining and lumber camps. It gave the wife a little money, and alfalfa butter a bad name.

Irrigated Lands.

The milk cow on the irrigated land milks for three hundred and twenty to three hundred and forty days of the year, instead of one hundred and fifty as of old. This has made a call for better cows, for those that would hold up in their milk for a long period.

The importation of improved stock has increased rapidly in late years; today the scrub sire is not seen. It is always an animal of good blood that is used. Half as many cows with improved blood will produce as much as the old scrubs did.

Alfalfa.

Alfalfa has always been considered as a plant suitable for irrigation, yet there are subirrigated lands, with an underlying basis of hardpan, that yield well without irrigation, the long tap roots reaching down to water.

These fields are held at high prices, nor it means all the advantages of irrigation without the expense. The irrigation companies claim their charges for water all the same, as they rightly say if all the water was out of the ditches there would be no subirrigation.

Irrigation.

There is land that is sold as irrigated that lies on ditches that carry no water after July. These limit the dairyman's crops of sorghum and corn and do not permit him to stock up to full capacity of a cow to the acre.

There are many men now supplimenting this lack of water by using wells. It pays to pump water from shallow wells for two irrigations of alfalfa. We put in wells during the dry years for the young vineyards, and pumped from them for a number of years, then they were idle for four years, then again in use, now are idle, yet they are there and with one of the gasoline engines we are safe from ever having a water famine.

Abuse of Water.

Irrigation is abused by using an excess of water. The new-comers into the state have to be trained to use less water and more cultivation. Winter saturation of the land with water and summer cultivation are the cheaper ways of handling the soil.

Saturate the land before corn planting time, then plow, harrow and cultivate until the soil is fine and mel-

low. Then furrow out four feet apart and plant the corn in the bottom of the furrow six inches below the level of the soil. Keep the cultivator moving to hold the moisture and when the corn is nigh enough, begin to crowd back the loose earth in the furrows around the corn.

When the corn is three feet high the furrows should be level. The corn by this filling in has been made a deep-rooted instead of a shallow-rooted plant, and the roots are down into the stored up moisture. When the tassels come, if the corn can be irrigated, plow out a furrow between every other row, and run the water in slowly to soak down deeply. Then as soon as possible cultivate. A corn crop grown in this way costs little and will give fifteen to twenty-five tons to the acre of silage. The time from planting to cutting is one hundred to one hundred and twenty days, according to the variety planted.

Over-irrigation.

Alfalfa suffers from over-irrigation much of the time. Watch carefully the growing crop, and if the crops on the levees of the checks show more than the intervals, then the crop has been over-irrigated. The cost of irrigating is in the labor, for in the alfalfa counties, the ditch companies receive 62½ cents to $2.00 an acre for water. It is paid whether the water is used or not.

The best time to irrigate is about ten days before the crop is cut. In the hottest weather, if the irrigation is done by moonlight or early in the morning, there is no danger of scalding. When alfalfa is not pastured it should be ready to cut every forty to forty-five days during the summer.

When it is allowed to stand too long a coarse, woody hay is produced, without lower leaves. The value is less for feeding and considerable weight is lost. Be prompt in making the hay and prompt in curing and removing it from the field. The next crop is already growing and it will not help it to have the hay cocks standing on it.

Beets for Food.

A change of food is valuable in feeding cows or pigs; a few acres in beets come in acceptably in the fall. They require more labor than corn to grow, yet beets and pumpkins feed well to both cows and pigs.

The dairy cow and irrigated land belong together; with forty acres of alfalfa a man with a family can live well and lay up a little money. Twenty-five cows, two horses, one hundred pigs, 250 chickens, with five acres in orchard and five acres of vineyard is the ideal little ranch of the working man. He can do most of the work himself and make a comfortable home.

Value of Water.

There are alfalfa lands held as investments by men living in San Francisco. They sell the hay for the southern market and claim that they often pay for the land and its improvements in three years' time, sometimes, in two years. Water was all the thirsty desert needed to become profitable for crops the dairyman grows for his cows, green crops to increase the milk flow, not water from the pump in the milk, but water into the green feed to make the milk. Irrigated land is good and desirable, but irrigated milk is "too thin," and the vendor is on his road to jail.

ALFALFA AND WATER.

Alfalfa seed may be sown in dry soil or soil that has been previously irrigated, the latter method being usually preferable.

It is better to have the soil in such condition as to moisture and tilth that the seed will germinate and the young plants appear without further irrigation being necessary. If the soil was dry when the seed was sown, or is not sufficiently retentive of moisture, or if, on account of the nature of the weather that follows seeding, the soil dries before the plants appear, water should be applied as promptly as practicable. The young plants must have plenty of water in order that a good stand may be secured.

After the young plants appear, they should be given water frequently enough to keep them growing steadily. The application of water twice a month during the first three months is usually ample to secure a good stand. If sown during the winter season mentioned above, a light crop may be cut three or four months after sowing. After this, the application of water once a month is sufficient the first season. It is probably not economical to apply water during November and December, but beginning with March, water may be applied freely to advantage, under the conditions existing in this state. Where water is available at all times of the year when needed for alfalfa, it will probably be better in most cases to postpone the free application of water until the first of April. Alfalfa being very deep-rooted, water to the depth of two feet may be applied to advantage just before, or during the early part of the growing season. After cutting the first crop, water may still be applied freely to advantage. After cutting the second crop the application of one-half to two-thirds of a foot of water will be sufficient for the production of each subsequent crop. But the amount that will be necessary to secure a good growth during the summer, will depend very much upon the amount applied during the winter. If the field has been thoroughly wet during the latter season, two good crops can usually be cut without irrigation between the first and second cuttings; and in some cases a third, or even a fourth crop can be cut. During the cutting season, the best time to apply water is a few days previous to mowing. By this method the new growth starts promptly after each crop is removed.

Alfalfa is especially adapted to a region with a fluctuating water supply, such as we have. When once established, the crop produced varies with the water applied within certain limits. Water may be applied freely during the winter when it is abundant, and withheld entirely during the summer. In fact, it will live during several average years without the application of any irrigating water. One field that has been under the observation of the writer has not been irrigated for over four years, yet many of the plants are still alive, a crop having been cut each spring the first two of the four years. Up to a limit of about six crops of two tons each, the amount that a field of alfalfa will yield increases with the quantity of water applied. A total of four to six feet can be applied to advantage during the year. It is not easily killed by drought, but it thrives under and responds to irrigation as satisfactorily as does any crop grown.

Irrigation in San Diego

IN RESPECT to irrigation as well as general topography, San Diego county is divided, by its central mountain ridge into two entirely separate and widely different sections; the desert and the western slope.

Our Imperial Domain.

In the former is the Imperial valley so widely known and well advertised by the sensational efforts to stop the overflow of the Colorado river into the Salton sea. For a time it appeared that the very existence i this section hung in the balance, but with the succesful outcome of the work done by the Southern Pacific Railway, its future may be said to be assured.

It is doubtful if any richer agricultural section exists—even the famous alluvial plains of Egypt can be no more fertile. With the whole Colorado river to draw upon the sources of supply for irrigation are more than ample for any possible need.

Western San Diego County.

The Western Slope of San Diego county extends from the Pacific eastward and up to the mountain ridge at an elevation of upwards of 6000 feet—a region well wooded with pines, firs and cedar trees. The rainfall ranges from an average of 10 inches at the city of San Diego, to one of from 30 to 40 inches in the mountains where the rivers find their sources.

As the Government records are taken at San Diego, a mistaken impression of the rainfall throughout the interior is given.

The topography of the county is of a broken and somewhat rolling nature. The rivers find their way from the mountains down through valleys, and often pass through narrow gorges, which form perfect sites for dams and storage reservoirs.

The San Luis Rey Valley.

The first river below the northern boundary of the county is the San Luis Rey, which rises in Warner's Ranch. At the point where it leaves this ranch, the Huntington interests are to erect a dam which will form a large reservoir. The primary purpose of this enterprise is the development of electric power, as there is an abrupt fall of some 1500 feet below the damsite.

The water after that will be used for irrigation on the lands below, which have been bought by this syndicate all the way down the river to Oceanside, thus controlling riparian rights.

From the San Luis Rey river also, water is diverted during the winter's surplus flow to the Escondido reservoir, which supplies the town and fertile valley of that name. This valley is a favored spot for oranges, lemons and grapes. The citrus fruits are irrigated; the grapes are not.

The San Diego River.

The next important river to the south is the San Diego river, rising in the Cuyamaca mountains directly to the east of the city of San Diego, and some 50 miles distant.

In the mountains, at an elevation of 5000 feet, is the Cuyamaca reservoir. This empties into Boulder Creek just below the junction, of which with the main river there is a diverting dam, which turns the water into the San Diego flume.

The water from the reservoir is only used to supplement the surface flow of the San Diego river in the late summer and autumn, and in very favorable seasons is not required at all.

The flume is of wood six feet wide, and conducts the water for 34 miles down to and around Lakewood and El Cajon on a contour line. The water supply of the city was at one time obtained through it and the thriving lemon orchards of La Mesa and Lemon Grove are irrigated from this source.

The Sweetwater River.

Next to the south is the Sweetwater river, which also rises in the Cuyamaca mountains on the south-eastern slope.

At a point about seven miles from San Diego bay, and on the river, is situated the well-known Sweetwater dam, which was, at the time of its construction, in 1887, the largest masonry dam in the country, and which is a very perfect piece of work.

The depth of water above the dam is 75 feet, and the reservoir contains seven billion gallons of water when full, as at present.

It is estimated that this amount of water will serve the territory dependent upon it for four years. This territory comprises National City, Chula Vista and the Sweetwater valley.

It is a pressure system, the water being conducted in iron pipes to each house and orchard to be served. This system is an advantageous one for the orchardist as the water is always on tap, and there is no waiting one's turn for the zanjero to turn it on.

The Spreckels System.

The last, and by far most comprehensive, water system on the western slope occupies the territory between the Sweetwater system and the Mexican line. This is the system of the Southern California International Water Company, and belongs to John D. Spreckels, whose interests in San Diego city and county are very large. This will be, when completed, the most comprehensive storage system in this state. The plan embraces four reservoirs.

1. The Moreno, at an elevation of 3000 feet, will impound 15 billion gallons. The Moreno dam is about half completed and is situated on Cottonwood creek, one of the headwaters of the Tia Juana river.

2. The Barrett dam, on the same stream below its junction with the Pine Valley creek, is at an elevation of about 1200 feet and will inpound 10 billion gallons.

Water will be discharged from the Moreno reservoir down Cottonwood creek to Barrett reservoir. From there it will be conducted in an open ditch or pipe over the divide to Dulzura creek down which it will run to the (3) Lower Otay reservoir, whose outlet is at an elevation of 400 feet, with a storage capacity of 14 billion gallons..

From it, water is carried through a 36-inch wooden stave pipe to the city of San Diego, which has received its entire water supply from this source since last summer.

Modern methods are in use to give the city pure water. Great pains are taken to prevent the growth of algae in the reservoir, and at the city end of the pipe line the water passes over

The Ornamental Garden

By ERNEST BRAUNTON

WATERING THE ROSES.

SUCCESS in growing roses depends in a great measure on how they are watered.

Roses, when overwatered, most generally show it by a soft growth with yellow, mottled foliage, and when not enough water has been given them they assume a grayish color, with small foliage and corresponding thickness of stem.

It is not a hard matter to keep between these bounds, however, but how much water should be given to derive the best results from the different varieties is where the art comes in; and it is only by exercising the utmost care that we can, to a degree, come near to it.

We should always have an object in view in regard to watering, its beneficial or detrimental results—not today, but in the future. Going to nature we find roses growing very luxuriantly, when the season has been favorable to them. True, outside conditions are far from those which we can maintain in the garden, still it is the wild roses for the wilds, and the garden rose for the garden.

There are as many roses not brought to their fullest perfection by insufficient watering, as there are others injured by overwatering. As our soils differ very materially as regards evaporation, the best course to pursue is to make careful trials, allowing a part to get on the dry side, then giving a thorough watering, keeping another part moist all the time, and so on. This can be done on a small scale and the best method will manifest itself in a very short time.

We must take into consideration the immense amount of evaporation that is going on through the foliage during bright sunshine. We often see the shoots drooping during a hot sun; this is the cause of the foliage giving off more moisture than the roots take up to sustain the strength of the plant at the same time; hence the necessity of spraying the plants overhead occasionally, though it should never be done, except the plants call for it. By so doing the extra quantity of moisture needed is supplied, and, instead of the plants becoming hard, with small foliage and thin, wiry wood, as would otherwise be the case, it allows the absorption by the roots to be utilized in building up a strong plant.

IRRIGATING FOR ORNAMENT.

Ornamental grounds are met with in all portions of the civilized world, but the most beautiful of these garden spots are found where irrigation is practiced, even in countries where irrigation is not necessary for ordinary agricultural and horticultural pursuits, and perfection itself is only attained where nature has provided the cloudless skies of summer and the mild temperature of winter, for in connection with these natural circumstances irrigation is a condition precedent to the successful cultivation of the soil either as a matter of business or luxury.

ROOTS FOLLOW MOISTURE.

Very striking examples of deep rooting as the result of vertical moisture penetration can be observed in some of our native trees, which, while naturally at home on moist ground, are nevertheless sometimes found forming luxuriant clumps on the slopes and even summits of our coast ranges and foothills. If we examine the ground where this occurs in the case of California laurel, we will generally find that the soil in which they grow is underlaid by slate or shale standing on edge, into the crevices of which the roots penetrate, wedging them open; while themselves flattening out, and thus penetrating to moisture at considerable depths. The same may be observed in the case of the erect "bedrock" or foothill slates of the Sierra, on which native as well as fruit trees flourish in very shallow soils, sometimes reaching permanent moisture at the depth of ten or more feet below the surface. It can readily be observed during rains that there is comparatively little run-off from the surface of these lands underlaid by vertical shales.

ESTHETIC IRRIGATION.

The average American citizen is accustomed to ask this question: 'Will it pay?" when considering any business proposition, and then to ask: 'How much will it pay?" and hence we have first considered the commercial side of the question of horticulture in connection with irrigation, to the exclusion of the esthetical view of the case.

But the American people are not given up entirely to the worship of the almighty dollar—whether it be gold or silver—and we find that the beautiful, the esthetic, the ornamental lawn and garden are being rapidly developed, not only in public parks and around the fine residences of the wealthy, but in front of and around the rose-embowered cottage of the laboring man, who seeks to provide the luxuries as well as the necessities of life for himself and his family.

MAGIC OF WATER.

Contrast for a moment the home comforts, the social privileges, educational advantages, the general state of society upon a bare and wind-swept prairie sustaining one family per square mile, with the status of a population of thirty families occupying the same space, amid the comforts, the certainties, the wealth which springs from that stolid and apparently inert soil at the magic touch of water; their homes embowered in trees and vines, surrounded by fruits and flowers, enlivened by the songs of birds and the hum of bees; rejoicing in the refreshing shade of green leaves, the soft carpet of luxuriant grasses, the sweet, low musical murmur of rippling streams and the plash of sportive fishes, leaping and playing amid the lilies in verdure-bordered pools.

BANKING PLANTS.

A bank of plants is beautiful, and in grouping the plants the taller ones should be placed at the rear, and filled in with smaller ones, sloping them in such a manner that there are no open spaces at or near the base of the group. In order to secure the solid effect, it is necessary to elevate some plants above the floor, by placing them on inverted pots or boxes.

All pots should be concealed by small plants, and in this manner you secure a mass of foliage in which there are no thin spots. For filling in, plants of low growth or spreading habits should be used; trailers should be used in a manner to bring the mass of green down to the floor, giving the bank the appearance of staring from the base instead of from the pots.—Florida Agriculturist.

The Vegetable Garden

By ERNEST BRAUNTON

GARDEN IRRIGATION.

A VERY important modification of the furrow system is the raised bed, which, under certain circumstances, is of great value in the vegetable and small-fruit plantation.

The raised bed is an elevation between two irrigating furrows. The field is laid off in narrow lands and several furrows thrown together so as to bring dead furrows about four feet apart, making long beds extending down the grade with their surface raised several inches above the old level. The motive is to arrange a plant bed with a water course on each side and below its surface level.

The whole plan is just the opposite of the depressed bed with raised ditches already described, and is obviously to meet quite different conditions. It is especially suited to a rather heavy soil in which water will move well laterally, rise well, and be retained. Irrigation is accomplished by holding water for a time in the ditches. Where the ground is sloping it is held in levels by dirt dams or by the cloth or metal dams already well-known, placed at intervals as required to raise the water nearly to the ground surface.

The arrangement has several advantages for the market gardener and is largely used by those of foreign birth, who rely upon hand work and desire to carry as many plants as possible per acre; for their rents for rich land near cities are usually high. It enables them to plant in close rows and in starting young plants it gives standing water along side, which they can easily flirt out with a pan or shovel when they think a little sprinkling is desirable. The Italian gardeners have a knack of doing this which is very interesting.

The chief advantages, however, are the distribution of water beneath the surface, which lessens the need of surface cultivation, and when the vegetables are well grown obviates the decay which comes to foliage by contact with a moist surface. The same is true of the use of raised beds for strawberries when grown on the heavier loams or when the light, shallow loams overlie hardpan and require frequent irrigation.

Another very important advantage of the raised bed lies in its adaptation to growth of vegetables and strawberries during the rainy season of semi-tropical climates. Not only is the raised bed more responsive to the greater warmth which comes to the air at intervals, and consequently promotive of winter growth of vegetables, but it also escapes the supersaturation which long rains may occasion. The deep ditches then act as open drains for the escape of surplus water. The system would seem to be widely available where there exists both the need of irrigation and the danger of excessive rainfall according to varying weather conditions.—Prof. E. J. Wickson.

There may be injuries by irrigation in the case of using excessive amounts of water a few days before picking. Walnuts are never injured by irrigation on land that has good under-drainage. The land might be leached out, perhaps, but there is no direct injury to the tree.

THE DEPRESSED BED.

The depressed bed, largely used in the growing of vegetables and small fruits, is really a form of rectangular checking.

In this case, however, the levees are widened so that they are not merely boundaries to confine the spread of the water to the inclosed areas, but they are also made to carry water to these areas by small raised ditches which are made upon their tops.

It is best for light, sandy loam, which has slight retentiveness and therefore loses moisture rapidly both by drainage and surface evaporation and must be frequently irrigated.

Shallow rooting plants like strawberries, which would perish by the methods of irrigation employed for them on more retentive soil, and which will be described presently, make very satisfactory growth and have a long fruiting season if grown in a depressed bed, especially if they are mulched well with rotten straw or coarse manure and the water allowed to distribute itself under this cover by admission from the raised ditch at several points at the same time.

The ditch at the surface level is much less satisfactory in such work; consequently it is run along the top of the levee. This arrangement is particularly adapted to very light soils, as stated, and especially in the hotter parts of the arid region, where water has to be applied once or twice a week to shallow rooting plants and where the shading of the ground by a mulch lowers its temperature and protects the roots from heat, which would be apt to destroy them in spite of the frequent use of water alone.

This recourse takes the place of mulching and sprinkling and is vastly better for a hot, arid locality. The sprinkled water flies off from the mulch with great rapidity and much water is used with little benefit to the plant, while the filling of the depressed bed from the ditch and spreading the water through and under the mulch is very economical of water and of most direct advantage to the plant.

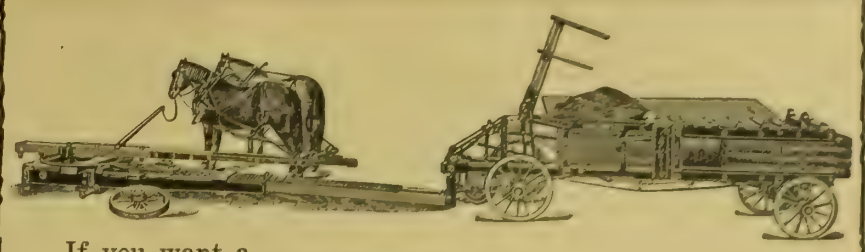
PRACTICAL IRRIGATION.

The man who knows nothing of practical irrigation may feel a sort of pity for the husbandman who is compelled to irrigate his crops in order to perfect them, but the man who cannot order his rain or moisture at will certainly has the pity of him, who with his hand on the headgate of his irrigation system, has absolute control of the elements so far as water is concerned.

SWEET CORN.

Sweet corn is generally planted in soil that has been previously irrigated, in some cases with a combined lister and drill, but more usually along small furrows through which water has been previously run, and that are left for the first irrigation. Some farmers, however, drop the seed into each third or fourth furrow as the land is plowed. When the corn has come up and the water applied previous to plowing and planting has evaporated, furrows are run between the rows for subsequent irrigation.

Carelessness in flooding trees in hot weather may injure them, but when judgment is used in irrigating, trees are not injured by water.



If you want a Haypress that will be a money-maker you should get a

Southwick

No question about it—it's the best press made. Note its good points—great capacity, perfect bales, ease of operation, durability, full 40-inch feed opening, long bale chamber, low bridge, self-feed, stands on the wheels when in use—a perfect press in every detail. We also have smaller presses—all steel, self feed. Write us today or call at our store.

Automobiles Need Roads

The automobile has come to stay. No matter how great may be the opposition to it by the farmers as a whole, and the liveryman as a class, it is winning its way into more perceptible popularity each year. It has so far overcome prejudice as to even find encouragement today in the independent farmer who sees in it the best friend the good roads movement has at the present time.

James W. Abbott, Ex-United States Commissioner of public roads, writing on this subject makes a strong appeal to the automobile interest to get in and boost the good roads movement with all its might.

"Having now reached the period when the motor car industry affects every possible department of human activity, what could be more logical than for that interest, as such, to take up the road question and proceed to solve it? No one can say longer that the automobile interest should hold itself in the background lest it arouse antagonism. The automobile interest has become IT in the world. The automobile needs good roads. It should combine its forces and get the roads."

The illustrations here given show a poor road before working and the same road after finishing. They need

A Poor, Flat Road Before Grading

"When the automobile captured the farmer it had conquered the world. The hayseed of other days may once have been correctly depicted in overalls and whiskers upon the board seat of a rickety wagon, holding the lines over a pair of venerable plugs. The passing of this type is, in my mind, the most important fact of the Twentieth Century to date. The farmer of today is the nabob. His mortgage has been paid off, he has money in the bank, travels for pleasure, and rides in an automobile. Not all of him, but enough to indicate with certainty the economic changes which are imminent. From this time on his interests square absolutely with those of the rapidly augmenting element to which the motor car has become an indispensable necessity. In the conquest, which is just ahead, for the commercial vehicle, the farmer will be strictly in it. The truck car will haul his products to rail or water; with motor devices he will plow, plant, sow, and till his fields and gather his harvests. It is easy to see what the commercial vehicle will do in every line of work. no further tribute than their appearance gives them. They are the most valuable adjunct to farm life at the present time. The automobile interest can help the cause of good roads mightily if it will.

Same Road Graded, Curved and Smoothed

This grade can be easily maintained with a little attention after heavy rains. When it gets hard it will shed rain quickly and thoroughly.

WHEN TO DRAG IT.

When the summertime is here,
When the corn is in the ear,
In the winter cold and drear;
Every season in the year;
Drag the road!

When you've nothing else to do,
Drag the road,
It will keep them good as new.
With a purpose firm and true.
Fall in line—it's up to you:
Drag the road.

Would you do the proper thing?
Drag the road.
Set the system on the wing,
Drag the road.
Give the drag a lively swing,
Toss the laurel-wreath to King.
Hats off! everybody sing,
Drag the road.

—J. L. Bollinger

Sometimes fruit trees are irriga continuously and never cultivated as to open the soil to sunshine a air. Such trees are not so stocky a strong.

The History of Irrigation

Irrigation of land, which to a majority of the American people of today is a new idea, is an art that appears to be almost as old as the culture of the soil by man. It was undoubtedly practiced for many centuries previous to any authentic written history. In the earliest traditions of the Chinese people, which are very ancient, irrigation is mentioned. In Egypt, Syria and the ancient kingdoms of Eastern Asia agriculture depended almost entirely upon irrigation, and still so depends. The Bible contains frequent reference to the irrigation of gardens, vineyards and fields.

The earliest agriculture of Europe, Asia and Africa began in arid lands, very similar to those of Arizona, New Mexico and California. In India, irrigation was practiced for many centuries by utilizing small streams and great rivers. As population increased, the storage of water was introduced. ravages of time up to the present day. In Spain, irrigation was also practiced by the Moors, and brought to a high degree of excellence.

On the discovery of this continent, the Latin invaders found the natives practicing on arid lands in Mexico, Peru and the southwestern portion of the United States. Remains of vast irrigating canals and and reservoirs in Arizona are believed by some antiquarians to be 10,000 years old. These invaders, who themselves came from an irrigated country, kept up the practice in a small way. It was not, however, until the Mormons emigrated to the arid wastes of Utah that irrigation on a large scale was undertaken by Americans in the United States.

Immense tanks, or reservoirs, and canals appear to have been constructed centuries before the Christian era. In the island of Ceylon alone are 5000 ancient reservoirs. Since the British have had control of the country, irrigation works have been constructed on stupendous plans, and thousands of old reservoirs have been restored. Over $360,000,000 have been expended on irrrigation works, one canal alone costing $15,000,000.

The remains of reservoirs in Palestine, which are supposed to have been constructed in the days of Solomon, for the supply of Jerusalem, show much engineering skill. The Phoenicians, at the height of their power, were celebrated for their canals. The Greeks at a very early age, paid great attention to hydraulic engineering. Ruins of large aqueducts are found scattered through Greece. Herodotus describes a conduit three feet wide, which was conducted through a hill in a tunnel a mile long. Another masonry aqueduct crossed a ravine 200 feet wide and 250 feet deep, and apparently had the form of an inverted siphon.

Rome, during the reign of Nero, was supplied with water by nine large conduits, having an aggregate length of 255 miles, and deliverin over 173,000,000 gallons daily, which amount was afterwards increased to 312,500,000 gallons, or 325 gallons to each inhabitant. The Romans were skilled in hydraulics. All houses had siphons, or water pipes. They drained the Pontine marshes, and made all their rivers navigable. In France, Spain, Portugal and other countries which the Romans conquered they constructed great aqueducts, many of which have defied the

CURRENT WHEELS.

In its simplest form a current wheel consists of a large skeleton roller made of wood, with paddles projecting beyond its rim. It is hung on a shaft and supported at both ends by piers or posts, so as to allow the wheel to dip into the water to the width of the paddles. The simplest device for raising water with such a wheel is a row of buckets placed on the rim so as to fill at the bottom of the wheel and empty into a trough near the top. A more complicated way is to connect the wheel to chain and bucket gear, or to a pump of some sort. These more difficult methods of construction are necessary in all cases where it is desired to raise the water to a height greater than the diameter of the wheel used.

Too much water continuously will check growth, turn foliage yellow and stunt the tree. The land should be cultivated between irrigations until there is but little moisture at the surface, but not allowed to become dry enough to curl the leaves. This will make healthier trees and a better quality of fruit than over-irrigated land, but the irrigation should be thorough and deep.

There are 35-year-old apple trees at the Hicks ranch in San Bernardino County, Cal., that have a ditch of water running constantly within 5 feet of the trunks and yet are very thrifty and bear nearly every year apples of highest quality. They will not grow, however, in a swamp, but must have some drainage.

Thousands of acres of trees and vines are seriously injured by seepage of water from ditches and the raising of water levels. Drainage of land to remove surplus water is one of the greatest needs in some localities.

CONSERVING WATER.

The late legislature of California had before it a bill to compel owners of flowing wells to cap them to save water from running to waste. The measure was one of merit, and the law ought to have been enacted years ago. That an enormous flow of well water is annually lost by neglect is evident to any observer of conditions surrounding uncapped wells. We recall seeing in Central California, several flowing wells from which the water was escaping in streams, water enough, if confined in one ditch, to have irrigated hundreds of acres of land.

In a country dependent upon irrigation this neglect is little short of profligacy, for the time will come, and that all too soon, when every inch of water will be needed to maintain the agricultural conditions of the state.

We are developing agriculturally so rapidly, expanding our irrigation ditches so fast and sinking wells so numerously, that we are gradually drawing from the ground the supply of the underground basins. This is not true of any particular section, but of all the territory where irrigation from wells is a necessity. The importance of conserving the water not absolutely needed in irrigation, is a vital one to the future prosperity of the whole state. Two years ago a commission appointed to investigate the water conditions in Southern California reported that there was a marked lowering of the level in the wells already in operation, caused by too heavy a demand for irrigating purposes. Since that time, however, the rainfall has been so abundant that anxiety on the score of water supply has been largely abated. But these conditions may not prevail with certainty, and the importance of judicious use of our basin water is apparent if we are to provide for future contingency. When we investigate the location of those areas, which show losses and of those which show gains, two facts which we should expect appear. The losses are in those areas where most pumping plants have been installed, and the gains in those areas of less intense development; and again, the losses are remote from the channels of the large streams, and the gains are near them. With two successive winters of heavy rainfall, ground water levels have recovered in favorable situations, and where pumping has not been extensive. While in less favorably situated or more heavily pumped sections declines have continued. With average rainfall it is safe to say there would be but a limited area that would hold its own. With substantially less than average rainfall, declines will be well nigh universal. As the situation stands now, ground water levels generally fall with average, and less than average precipitation. They partially recover only when the rainfall is well above the average. It is then the part of wisdom only to use every precaution not to tax our underground basin supply beyond actual need, for if we do, and our average rainfall declines, the country will face a serious water famine in the agricultural districts. Retain, therefore, all water not actually needed, in the ground basins, by capping flowing wells.

OUR INLAND RIVERS.

The movement inaugurated by President Roosevelt, having for its purpose the development of a comprehensive plan for the improvement and control of the inland rivers of the country, has awakened the keenest interest of the people in the states through which these rivers flow. To exploit this scheme he has appointed an Inland Waterways Commission consisting of Theodore E. Burton, chairman; Senator Francis G. Newlands, Senator William Warner, John H. Bankhead, Gen. Alexander Mackenzie, Dr. W. J. McGee, Mr. F. H. Newell, Mr. Gifford Pinchot and Mr. Herbert Knox Smith. In his letter to Congressman Burton, notifying him of his appointment, the President refers to the inability of the railroads to afford prompt transportation to the products of the country, and the necessity of providing a complementary water system, a subject which has received but scant attention in the past. The commission, he says, should consider the relation of the streams to the use of all the permanent natural resources, and their conservation for the making and maintenance of prosperous homes. He also believes that any plan, to be feasible, should recognize the means for executing it already in existence, both in the departments of the federal government and in the states and their subdivisions.

The improvement of the great streams of the Middle West, like the Missouri and Mississippi, will afford an outlet to the congested transportation problem of that region and result in the saving of millions of dollars to the farmers. So if the Sacramento and San Joaquin rivers in California could be improved, especially the Sacramento, as far as Colusa, the country thereabouts would witness such a marvelous increase in industrial and agricultural resources, as to make it the peer of the state in a brief period of time. The Nation will profit by the proposed development of its waterways, while the railroads will not suffer, as they have demonstrated their inability to take care of the frieght which the producers seek to market.

TIMELY ADVICE.

As a matter of precaution simply, the Cultivator has urged the farmers of the Pacific Coast to beware of incurring heavy debts. There may not be any shrinkage in values within the next year, or so, and there may be, we cannot tell that at this time. But the safe rule is to keep well to shore thus avoiding possible loss or inconvenience by any falling of prices in land values.

There comes to our attention the following timely advice offered by the Salinas Index, which is along the line the Cultivator has argued for more than a year.

We quote: "Caution should certainly be observed until the next crops are assured, for we have been blessed for six fat years and experience shows that the lean years must follow. The high price of farming land in many states is based on present high prices of farm products and large crops, and in many cases the prices asked for farms will, under the most favorable conditions, only pay very reasonable interest, and with lower prices and shrinkage in crops would make but a very poor return on the investment. The farmer who is in debt might, if crops are poor, find himself in difficulties, and now, therefore, is the time to get out of debt, so as to be on the safe side if business depression arrives."

RELATION OF IRRIGATION TO FRUITS.

(Continued from First Page.)

which appeal to the fruit eater and for characters which win the fruit trade, has long been in controversy, and the prejudice against irrigation from these points of view has been most outspoken.

This prejudice still exists in the minds of those who have not had opportunity for careful comparative judgment and no experience to distinguish between properly irrigated and excessively irrigated fruit. Of course, theoretically the best fruit must come from the tree which has moisture continually present during its growing period in the amount required for perfect development of its fruit.

Too little water for such perfect growth would injure the fruit and too much water would also injure it, and although the injuries proceeding from lack and from excess might be different, they would all render the fruit defective. But there have been prejudices against irrigated fruit which have been slow to disappear even among fruit growers who might be presumed to have the best opportunities for speedily reaching sound judgment on the matter.

The first striking character of irrigated fruit to attract attention was unusual size, and such size was often found to be unmatched by richness and flavor. Medium-sized fruit was better to eat.

The general conclusion then was that water artifically applied made a fruit fine to look upon but not otherwise desirable, and from this single observation arose the quite general opinion that the farther it departed from largeness the better the fruit; therefore the smaller the fruit the richer in sugar and the more refined the flavors and aroma.

It is difficult to replace this opinion by urging theoretical considerations of the actual need of the plant for a continually adequate moisture supply, nor do the determinations of sugars and essences by fruit analysts nor the awards of exposition juries convince all whom they reach. It seems desirable then to cite general experience of those who judge fruits by ordinary sense methods or by commercial standards in order to determine whether such experience reinforces the conclusions reached by those who approach the problem along lines popularly distinguished as "scientific." This was the motive in the inquiry upon which this report is based.

The attempt was made to secure the results of the experience of fruit growers, some of whom could give comparative judgment and others of whom perhaps had grown only irrigated fruit and could speak positively from experience as to its suitability for various commercial purposes.

Although the writer was aware of the general change in the mind of growers toward the use of water even in regions of considerable rainfall, he must acknowledge that the declaration of the benefits of irrigation in developing desirable qualities in fruit is sharper and wider than expected and there can be no question as to the impression and influence which will follow the publication of such testimony.

The testimony certainly establishes beyond question the quality and commercial standing of irrigated fruit through more than a thousand miles of distance along the Pacific Coast. In this distance the conditions range from fairly wintry to strictly semitropical, and from fully arid to quite humid, judged by the annual rainfalls in the different localities. In all these wide ranges there is the evidence of extended experience that irrigation improves fruits in all respects, provided water is supplied at times and in amounts which trees under the different circumstances require for the best discharge of their fruit-bearing function. Obviously there are conditions under which irrigation is unnecessary, and there is irrigation practice which may tend toward the development of some desirable characters and the loss or reduction of others, but these facts do not militate at all against the wise use of water.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Crops in the vicinity of Elizabeth Lake look extremely promising.

Brawley is one of the best places in the country to raise Bermuda onions.

Conditions in Ventura county are favorable for a large crop of beans and high prices.

Several owners of fine animals are proposing that a horse show be held in Imperial this spring.

The melon acreage at Brawley is close to 1,000 acres, with between 700 and 800 acres of good stand.

The Imperial valley will ship ripe cantaloupes the first week in May, thereby breaking all records for earliness.

Two cars of fat sheep and five cars of fat cattle were shipped from Imperial last evening to the Los Angeles market.

For the first time in many years farmers in the southern part of the state are complaining bitterly of too much rain.

Practically all the bean land in the state has been badly damaged except the lima bean lands south of the Tehachapi.

Mr. Schulte has twenty-eight acres in cabbages in the Orangethorpe district and believes his crop will average at least ten tons to the acre.

There will probably be somewhere from ten to a dozen carloads of grapes shipped from Imperial during the few weeks following soon after June 1.

The Imperial creamery Saturday made 1400 pounds of butter, breaking the record. The average output of the creamery is now 1100 pounds a day.

The farmers of the Montalvo section are progressing very rapidly with the cultivation of their farms, and a record-breaking bean crop is anticipated.

There is a good prospect that the planting of about 1500 acres of grapes at Imperial, during the past winter, will be exceeded during the coming winter.

Shearing sheep is now going on at the Moulton ranch east of Tustin where about 12,000 sheep are undergoing the process of being shorn of their fleecy coats.

Leading cabbage growers do not believe there will be over 450 carloads of cabbages in Olive, Fullerton, La Habra and Whittier belt. The estimate early in the season was 600 cars.

A series of investigations, to be carried on permanently by the Bureau of Soils of the United States Department of Agriculture, will be commenced in this state at once by Mr. W. W. Mackie, who has arrived from Washington, D. C.

The cabbage output of the Fullerton-Whittier district last year was about 500 car loads; many acres of early cabbage this year will not run over from two to three tons per acre; in some places the heads are running to seed largely.

At the Minnesota dairy convention H. J. Roseau spoke on educating the farmer to produce good milk and cream. The patron must be made to see the profit in his own pocket for caring for his milk. The higher prices obtained for extra creamery butter, the larger price the creamery can pay for butter fat.

E. F. Pember, in the Dairy Farmer, says that no farmer has any right to expect ideal milk and beef production from the same cow. He should not be satisfied until every cow is a pure bred one of some sort.

A very good cure for a cough is oil of tar. Give teaspoonful each morning when you first find your horse coughing and it will usually cure the cough and prevent distemper. It is cheap, simple and effective.

Never allow two foals to feed out of the same box. One is sure sooner or later to become master and secure the lion's share.

HORTICULTURE.

Redlands sent forward a total of 135 cars of oranges last week.

Redlands has shipped very close to 2000 cars of oranges this season.

The acreage in walnuts in California is 4275 bearing and 2120 non-bearing.

Last year the walnut crop of the Fullerton-Placentia Association sold for $170,000.

Los Angeles county has 865 acres of apricots; Orange, 2030; Riverside, 570; San Diego, 400.

The state acreage in olives is put at 10,800, of which Los Angeles reported 2250 and Butte 1050.

The amount of water now being used in the irrigation of Imperial valley is breaking all records.

The totals of the apple orchards in the state figure out 13,700 acres of bearing orchard and 6900 of non-bearing.

On Saturday the four packing-houses of Fillmore had ten cars of oranges packed, but were unable to get any cars to ship them in.

Reports from Rivera and Whittier say that there will be a larger walnut crop in these sections than last year if the weather is favorable.

The acreage in plums for the entire state is given at 7490 bearing and 2250 non-bearing. Other varieties of prunes are put at 110 acres.

Walnut blossoms in the south are now beginning to "set" and if the weather is favorable for the next few weeks, the crop promises to be larger than last year.

The annual report of the State Board of Equalization gives some very interesting figures regarding the acreage in fruits and nuts in the various counties of the state.

Messrs. Carnes and Maskew this week liberated several colonies of the newly imported parasite for red and purple scale in Wm. McLauchlin's orchard at West Anaheim.

The Monrovia-Duarte Fruit Exchange has distributed to its patrons $30,000 in dividends accruing from the sale of oranges. The second dividend for February amounted to $9000.

The following is our southern walnut acreage: Orange county, 2385; Ventura county, 1375; Los Angeles county, 920; Santa Barbara county, 440; San Luis Obispo county, 410.

The citrus fruit in Southern California which has not yet been picked is in better condition than it usually would have been at this season. The cool weather and continued rains have kept it firm and sound.

The cold and rainy weather has spoiled whatever chance might have existed for a good crop of apricots, and the condition of the rest of the fruit is more or less problematical, it being too early to determine what loss if any has been occasioned by the continuous storm.

RAINFALL.

Healdsburgh has had for the season 42.91 of rain against 36.97 inches this date last year.

Lindsay has had 11.86 inches of rain against a total for last season of 20.52.

Vacaville has had rain for the season up to 26.68 against 23.62 for the same time last year.

Dinuba has had 14.15 inches of rain, considerably more than any year in the last ten.

Since September 23 to date, 18.39 inches has fallen at Mt. View as compared with 12.77 inches during the same period of last season.

Watsonville has had 38.42 inches of rain.

Too much or too frequent flooding around the tree with too little cultivation between irrigations may do injury. Too many people who have plenty of water use it too frequently, thinking to escape the trouble of cultivation.

Northern California

AGRICULTURE.

The overflow in the river district has put all of the dairies in that section near Dixon out of business.

There is good profit in raising sugar beets in San Joaquin county and many carloads will be shipped from Lodi this season.

The Tehama county wool this season is said to be of very good quality and is expected to sell for from 20 to 22 cents.

The devastating floods of the Sacramento and San Joaquin rivers during this winter have made the bean market extremely firm.

The Ukiah Chamber of Commerce has taken up the matter of establishing a creamery for the sole purpose of assisting the farmers.

Mules are being shipped from Orland at a rate that promises to create a big shortage for the work in the harvest fields this summer.

Some large farmers in the San Joaquin didn't get in any grain. One farmer, who had in 2000 acres last year, has only 75 acres in this year.

From all indications the grain crop will not be over twenty-five per cent. of the usual crop in the northern section, as there is but little wheat sown.

A grain buyer who does business in Merced and adjacent counties estimates that only 30 per cent. of the usual area was sown to grain this year.

The rainfall record for March was broken at Ukiah, the total being 18.18 inches. The greatest previous record for the month, was 14.47 inches in 1879.

Many acres of bean land in Central California is still under water and cannot be planted to beans this year, and on that account a shortage is expected.

It is expected the wool market will open at Red Bluff soon, as the sheep men are now shearing their flocks and the first load of spring wool came in Tuesday.

There are many acres in the Woodbridge district that on account of the recent inundation it will be impossible to raise other crops than sugar beets this year.

S. N. Mathews of Salina shipped 200 head of stall-fed steers to the Western Meat Company of San Francisco. One steer weighed 2130 pounds and brought $95.75.

In Yolo county the farmers have taken steps to organize a local insurance company under the laws of the state, and already have over $100,000 of insurance offered.

L. P. Denny recently sold five carloads of cattle off his ranch near Corcoran. Among the lot were two Angus steers less than one year old that weighed 910 pounds each.

Some of the farmers owning lands down on the river south of Red Bluff have gone into alfalfa extensively and are now installing electric motors and pumps with which to irrigate the coming season.

There are 4661 bales of hops unsold in Ukiah valley and the price seems to be going up. Several sales at 9½ and 10 cents have been made in Santa Rosa and it is reported that 11 cents has been offered.

The cause of the shortage of grain crops in Central California is the fact that after the ground was moist enough to plow the rains were continuous and, for the most part, prevented plowing and seeding.

The state farm at Davisville will be the scene of much activity during the present year. A contract has been awarded by the state board of regents for the erection of two cottages at an outlay of $6751.

The last legislature appropriated the sum of $132,000 to provide for the erection of buildings, improvements, the purchase of furniture, supplies, machinery and livestock, and to pay the running expenses of the state farm at Davisville.

HORTICULTURE.

Another large winery is to be erected at Healdsburg between now and vintage season.

An orange sale in New York netted a Lindsay grower $764.57 for 384 boxes of navels and seedlings.

Grape vines in the north are not yet far enough advanced to make a guess on the crop possible.

Curled-leaf is making its appearance in peach orchards above Orosi, the Alberta showing up worst.

The recent floods about Lodi have exterminated by drowning fully 50 per cent. of the larvae of the grape leafhopper.

The apricot crop will be a total failure, while prunes will suffer forty per cent. loss in the Santa Clara valley.

Peaches will be a light crop about San Jose. So far as ascertained other fruits will be above normal in their output.

A report has been received at Porterville of the sale in Minneapolis of a car of oranges belonging to E. E. Graham for $832.

Apricots about Gridley will probably prove a failure, but the almond trees are holding out surprisingly good prospects for a crop.

The bright weather of the past few days is encouraging and fruit growers about Gridley are confident of a good stand of peaches.

Curl-leaf and peach blight, two well-known dreaded diseases to fruit men, have been found in a number of the orchards near Visalia.

Prunes in the north were not far enough advanced to be hurt by the heavy rains and it is thought that the crop will be a normal one.

The chances of the grape growers in San Joaquin county to supply California with raisins and table grapes this summer are most encouraging.

Messrs. Holmes and Sweet, soil experts, are now engaged making a survey of the soils north of Williams extending from the foothills to the Sacramento river.

The state forester is in Lake county assisting in the preparations of plans for the extensive planting of eucalyptus trees on a tract of barren land in that county.

A. J. Delaney's car of oranges contained 382 boxes and brought free on board at Porterville $887, from which Mr. Delaney netted above packing charges $742.90.

The parasites which have been kept on cold storage in the state hatchery during the winter months, will soon be taken out into the orchards and given a chance to hatch out and mature.

Among the buildings provided for the Davisville state farm are a dairy building, livestock pavilion, dormitory, barns, green-houses, propagating-houses for horticultural and viticultural purposes, necessary cottages, fences, etc.

The largest improved property deal in the history of the orange belt of Tulare county was consumated last week at which time the Camilla Ranch just east of Lindsay was sold to a newly organized company of local and Eastern gentlemen for $250,000.

It is too early to make anything like a correct estimate of the fruit crop for the coming season in Vaca valley, but at the present time late blooming plums, and cherries, grapes, French prunes and Bartlett pears look promising; peaches will be light, and apricots are practically a failure.

Since the fruit growers in this locality have combined to resist the exorbitant demands of the Japanese laborers, this class of help has not been quite so independent. The test will probably come when the season is at its height and fruit ripe on the trees. Then the growers should form a stronger compact so as not to be at the mercy of the little brown men. Good white help is preferable at all times if the same can be secured.—Sutter County Farmer.

Buy the World's Famous Egg Food No. 4

Midland

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clork Exposition."

Profit in the Poultry Yard

By Mrs. A. Basley, Hollywood, Cal.

WATER FOR POULTRY.

WATER! water everywhere and not a drop to drink!" was the sad refrain of a pen of hens. They could both see and hear the limpid water coursing along the furrows to irrigate the nearby oranges and why, oh! why, should they be limited to a little drop of foul smelling, warm liquid at the bottom of an old tin lard pail, when there was water in plenty so near? Did the green oranges need it as much as they?

Importance of Water.

This is not an imaginary picture, it is one that I am sorry to say I have seen with my eyes and the cruelty of it made my heart ache. "It is an insult to demand eggs from fowls kept under those conditions," was my remark to a friend.

Few realize the importance of water, pure, fresh water for hens. How would the best and cleanest of poultry keepers like to go out and take a deep draught of the same water that their hens are condemned to use?

Dr. Sanborn in writing on this subject says: "Impure water is the cause of many sick birds. All birds drinking bad water do not become sick. If they did, letters to poultry editors would be too many to answer. Towns and cities known to be healthful are sure to have a pure water supply, and poultry plants that are known producers of sturdy birds are careful to supply clean water. Not only must good water be given, but the dishes must be kept free from filth. Water is so cheap and so easily given, that it seems a pity that so many seem to think it is something to be supplied or not, as is convenient."

No Water, No Eggs.

"Hens insufficiently supplied with water are poor layers, and if the available water is bad, they are in a condition to contract disease because of their lowered vitality. Filthy water is a good carrier of catarrh, roup and cholera germs. Cleaning daily the water dishes and giving fresh water diminishes the danger of these severe diseases getting a foothold.

"Many a promising lot of brooder chicks have died solely owing to being obliged to drink warm, filthy water, while the owner of the birds comforted himself by thinking that the diarrhoea must have been owing to a cold."

Dirty Water Makes Poor Eggs.

Irrigate your land if you wish, but water your poultry first! I have spoken of the humanitarian side, of the cruelty of not attending to the wants of your fowls; now let me show how it affects your pocketbook. Lack of water lessens if it does not entirely stop the egg yield. The contents of an egg are nearly seventy per cent. water!

Almost three-fourths of the eggs that you ate for breakfast were composed of water. Was it clean water or dirty? "Can you let me have some eggs for breakfast?" said one neighbor to another in my hearing a few days ago. "No! but I can get some from Mr. Vulcan," was the reply. "Oh! I don't want any of his eggs, they have such an unpleasant taste!" Dirty water!

Some years ago when I was in the poultry business my doctor came to me with a request to take some eggs to a patient of his. When I took her the eggs she said: "I have not tasted a nice flavored egg since I came to California, they all taste of dirty water." Mine, however satisfied her.

Hens are Two-thirds Water.

Scientists have analysed the body of a hen and have found that the very large number of different substances found in her may be grouped under four heads: (1.) water; (2.) mineral matter; (3.) protein, or nitrogenous matter; (4.) fat.

Water is the largest of these, and amounts to about sixty to sixty-five per cent. of the body of the hen. Nearly two-thirds of the hen are water. Dirty water or clean water? Which?

If you want well flavored fowls for the table give them plenty of clean fresh water. If you want delicious eggs see that the hens have clean water to drink, and keep that water shaded in the summer time.

Hens are often called egg machines, and they are the only machines that do lay eggs. If you want nice tasting eggs you must surely put into your machines the food, and especially the water, that is pure and good. Three-fourths of the egg is water; if the hen lacks water, she cannot make the egg, and will stop laying, and if the lack of water is continued she will soon become a very poor layer, even if no other ills befall her.

Water for Chicks.

I begin by giving my little newly hatched chicks water, even before feeding them. Nice little drinking fountains can be bought at the poultry supply stores.

I prefer those that can be scoured and scalded, but I often make them myself out of a tomato can or baking powder can by making a hole with a nail in the can about an inch from the edge, then filling it with water or milk up to the hole, inverting a saucer or a small pie plate over it and holding the saucer firmly, I quickly turn it over, the water leaks through the hole into the saucer, the chicks can drink, but do not get their little bodies wet.

Or I take a tumbler, fill it with water, and invert it with a saucer, then slip a small bit of wood under the edge of glass and the water will leak into the saucer.

For half-grown chicks, a bottle can be used (a quart or pint bottle). A frame of some kind must be used to hold the bottle with its mouth down in a saucer or shallow vessel.

I find an easy way is to tack a bit of wire upon a post or the side of the house to hold the bottle upright or I put the wire inside a small box so as to keep the bottle in the shade. The mouth of the bottle should be about one-quarter of an inch above the bottom of the saucer. If you cannot suspend it in this way, bend a stiff hairpin and insert it in the neck of the bottle so that it will keep it a little above the saucer.

Water for Hens.

For the old hens, I prefer a large crock, or I use gallon or two gallon kettles. I bought several dozen of these porcelain-lined kettles some years ago at a sale and have found them very useful. I buy little sink brushes, half a dozen for a nickel keep those in the pens and scrub out my kettles at least once a day. It is very quickly done and I know that my good biddies are having as clean, fresh water to drink as I myself.

A word of warning about "irrigating chickens:" do not let the water run from one pen through the others. I knew a man who thought he had a very fine system of watering his fowls; he had a small stream of water running night and day through his pens, unfortunately he got roup into the top pen and it spread through the whole ranch; he had 3000 hens, but he had to go out of the business on account of the water carrying the infection.

I saw at Fullerton, lately, a very good plan for watering fowls, a shallow saucer-like basin with a faucet above it constantly dripping, the basin is surrounded by a little pavement of cobblestones through which the water that overflows sinks so there is no mud puddle and the fowls have a constant supply of fresh water.

Water for Ducks.

For ducks, after trying various plans, I found one that did very well. I had a barrel sawed in two. Two-thirds in one end. This two-thirds I knocked the head out of and I buried the barrel, setting the one-third part over it with the bung hole in it.

I had a broom handle, which fitted in the bung hole and every day I let the dirty water run through this hole into the bottomless barrel and it soaked away. In this way I gave my Indian Runners fresh water and a small bath every day. I found if I sawed the barrel exactly in half that it made the top part deeper than I wanted.

DON'T FEED the little chicks anything for the first twenty-four hours. Then feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seed, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it all up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. For sale by many dealers. If yours does not keep it, try another, or send to us and we will see that you are supplied.

How to Raise Young Chicks

The difficulties encountered in raising young chicks are numerous. Disease and lice are said to destroy nearly 50% of the annual poultry crop. Errors in diet and unsanitary conditions also help to decrease the poultry profit. But you do not need to suffer these losses if you will give poultry half the care you give other stock. Besides

DR. HESS POULTRY PAN-A-CE-A

is guaranteed to prevent and cure gapes, cholera, roup, indigestion, etc., allaying fermentation and destroying the germs of disease. By its special tonic properties it increases the powers of digestion and assimilation and compels the system to appropriate the maximum amount of food to egg production, also making the young grow fast, healthy and strong. Besides increasing growth and egg production Dr. Hess Poultry Pan-a-ce-a has special curative properties peculiar to itself. Take no so-called poultry food as a substitute. Remember that Dr. Hess Poultry Pan-a-ce-a is the prescription of Dr. Hess (M. D., D. V. S.) and bears the endorsement of leading poultry associations in the United States and Canada, and is **sold on a written guarantee.** It costs but a penny a day for about 30 fowls. Feed Poultry Pan-a-ce-a as directed, sprinkle Instant Louse Killer on the roosts, nests and into the dust bath, and we guarantee you will have no loss from disease. **1 1-2 lb. package, 35 cents; 5 lbs. 85 cents; 12 lbs. $1.75; 25-lb. pail $3.50**

BUFF ORPINGTON DUCK LAYING.

We can but speak words of praise for this new variety of duck originated by the late Wm. Cook.

Ours are an imported trio, 1905 hatched birds, and were brought over from England last year; since being in our possession here in California, the two ducks, in five months, have laid 224 eggs, or a total, from the first egg laid Oct. 8th, of 248 eggs in 145 days.

The eggs have proved very fertile, and with very few misshaped eggs in that lot. The record from Oct. 8th, for that month is 24 eggs; November, 49; December. 49; then they were shown at "The Breeders' Show" first week in January, which broke them up laying; it is possible some eggs might have been laid during that period.

However, they began laying again on the 12th; laying 31 eggs in January, 48 in February, and 47 in March.

The young ducks grow fast and drakes are marketed at five pounds. If off-color or not retained to sell for crossing on Runners, will run possibly one pound lighter than good Pekins, are a larger duck than Runners and considered in England a very superior table duck.

The plumage is a soft brown, some run light in color and others dark and some shade into a blueish-gray. The color is not a true golden or orange buff as in our buff fowls. Heavy laying has a tendency to bleach out the plumage to a drab. They are very docile indeed, and will stand all kinds of rough treatment, to say nothing of a five or six thousand mile journey by boat and rail.

Mrs. Plaw of Fruitvale can attest to this also; she has imported them direct from England and bred and exhibited them for several years.

In carriage they are not as erect as Standard Pekins or Runners, but have good length of body and breadth at shoulders; the drakes have a rich seal brown head, should be free from white in any part of plumage, primaries included.

A green head or wing is a serious defect; the drakes' bills run from a dark green with black bean to a greenish horn, or orange horn color. Tne ducks have a dark horn-colored bill; are medium in size, broad and rather wider at ends.

They proved their superior merits in Australia two years running, in a competition got up by "The Australian Hen;" winning over all breeds in first season's test, and coming within 4 or 5 eggs of winning the following season. Their eggs are white, similar to Runners, and sell as readily for market. Of course our eggs are all incubated either by us or others and with good results.—A. G. Goodacre.

Large shipments of eggs are being made every day from Folsom. One of the chicken raisers finds a ready market in Tonopah, Nev., where he receives an advance of several cents over the local market price.

HOUSES AND YARDS.

We take it for granted that you have your land and will work on a basis of one acre, all to be used for poultry. Your yards should be 25x48 feet. This will give you 43 yards to one acre with 4 feet alley between yards. The yards should be enclosed with 5 foot poultry netting. In each yard should be a house 4x6 feet and also a scratching pen. Each yard will hold twenty hens; but you should not have more than 400 hens per acre if you expect to raise young stock, for at least one-half will be required for the latter. The material for a good, cheap house, constructed to house about twenty fowls will cost $6.00. The house should be 4x6 feet, built of one-half inch lumber, with gable roof, door in end and no floor. Sides of house should be 4 feet, and be raised about twelve inches, which will afford ventilation and keep the ground from getting foul. Put your roosts about one foot from bottom of house made of 1x3 inch stuff, about 15 inches apart, made so they can be removed for white-washing.

FARMERS AS POULTRY-MEN.

One of the most serious handicaps that the American farmer has to carry, is the regular annual hen strike. Just as often as the sun crosses the autumnal equinox, just so often Mrs. Hen refuses to do any more business, and leaves Mrs. Farmer with no pin or grocery money. From that time 'till the sun warms the north side of the barn, there is very little "doing" in fresh eggs, and prices soar. We are quite inclined to take this regular yearly "shut down" as necessary, and put up with it, just as we do with the high price of coal. But it's a mistake—there is no more need of suffering that loss than there is of standing any other sort of "bunco" game. Mrs. Hen can be made to understand and do her full duty, if you do your duty by her. Did you ever observe our hens closely during this "off" period? If not suppose you do, next time it occurs. You will find them dull, listless, logy and slowly shedding their feathers. Now moulting is a natural and necessary period in the round of the hen year, but it need by no means be a time of total loss, and if you intend to get your share of the profit sure to come from a constantly increasing demand, you must cut this non-productive period down as much as possible.

The proper thing to do with hens in order to avoid this lost time is to give regularly a small amount of Dr. Hess Poultry Pan-a-ce-a in the morning feed. I do not hesitate to say that there is nothing so well adapted to the poultry-man's need, as this preparation. Dr. Hess studied every possible phase of the "hen problem" by scientific research and careful experiment under just the conditions which poultry-men are compelled to meet, and Poultry Pan-a-ce-a is the result.

If you are not acquainted with Dr. Hess Poultry Pan-a-ce-a and what it does, let me say first—it is not a stimulant; it does not excite the hen to an unnatural and artificial production of eggs. It does, however, compel every organ to act in a natural and healthy manner by causing the hen to digest and assimilate the largest possible amount of food taken, so that laying becomes a fixed and constant habit. Poultry Pan-a-ce-a makes rich red blood and supplies the nitrates necessary to assist in throwing off poisonous matter from the system, so that health becomes a natural condition in confinement as well as in liberty. I do not hesitate to say that no flock can be diseased when Dr. Hess Poultry Pan-a-ce-a is regularly given.

If this course is begun with young chicks and followed consistently every day, growth will be rapid and loss practically nothing. I have known pullets handled in this way to begin laying in October and continue productive through the entire winter, and as I said before it shortens the non-productive period for old stock. Dr. Hess and Clark are so certain of the value of their Poultry Pan-a-ce-a that they give a written guarantee with each package; if it does not give results, it costs you nothing. One cent's worth of Poultry Pan-a-ce-a will make it a daily feed for 30 fowls. If you use it as directed, and occasionally sprinkle roosts and nest boxes with "Instant Louse Killer" your success will be ample.

Chamberlain's Perfect Chick Feed

World's Chick Feed of To-Day. The only original **Dry Chick Feed.** All others are worthless imitations. **Chamberlain's Perfect Chick Feed** was used exclusively at the great St. Louis World's Fair during the 7 months. This is the highest compliment paid to any manufacturer of poultry food in the world. Perfect Chick Feed also endorsed by the U. S. Experimental Station and the Columbia School of Poultry Culture. All the leading poultry men of the country use Chamberlain's Perfect Chick Feed on its merits.

NOTHING JUST AS GOOD.

National Irrigation Congress

The Fifteenth National Irrigation Congress, which will be held in Sacramento, California, September 2-7 next, will be a very important and valuable session. The people of Sacramento are already making preparations for the event. A managing committee or Board of Control has been created, and office established and the work of providing for the comfort and entertainment of visiting delegates is well under way.

Plans and Prizes.

The plans for the event include an Interstate Exposition of Irrigated Land Products and Forestry, in which all states having Irrigation and Forestry interests have been invited to participate. It is announced that handsome trophies and prizes will be offered for state and individual exhibits of all kinds of irrigated products, also for exhibits of forest products and minerals.

The National Irrigation Congress is composed of delegates representing Farmers' Clubs, Irrigation Societies, Chambers of Commerce and other organized commercial bodies, cities, counties and states. The meetings are held annually and are attended by delegates from all parts of the United States. Among those who attend are United States Senators and Congressmen, Governors of states and other high officials of National and State Governments, as well as practical farmers, irrigators, stockmen and lumbermen.

Purpose and Place.

The purpose of the Irrigation Congress is to promote the development of wise and beneficial National Irrigation and Forestry policies, as well as to provide for discussions of practical details of Irrigation and Forestry. Great and valuable results have followed the work of the Congress in the past, and with the growing importance of and increasing interest in National Irrigation and National Forestry, still greater importance attaches to each succeeding session.

Railway companies have been asked to make special rates of fare, and special freight rates for exhibit materials intended for exhibition at the Interstate Exposition, and it is expected that extremely low rates will prevail. Sacramento, where the Irrigation Congress will be held, is the capital of California, an important railway and commercial center, but chiefly important from an agriculture standpoint by reason of the fact that it is located in the heart of the great valley of California, within which lie the greater portion of the farming lands of the state. A thousand-mile excursion through this great valley is a part of the plans for enabling delegates to see California farming and California irrigation.

Some grapevines have been killed —apparently by too much water.

IRRIGATION BY SPRINKLING.

Irrigation by sprinkling is a method which, so far as the writer knows, is not pursued for any commercial purpose in the irrigated regions of the country. It does, however, sustain itself on the ground of commercial advantage in the Eastern States, as has recently been shown by Professor Vorhees, and the data which he presents should be carefully considered by those who contemplate recourse to irrigation as a protection to high value crops against occasional deficiency in summer rains.

Orchards and vineyards are killed by over-irrigation, because of the raising of the water level too near the surface.

Columbus Engines

Have Stood the Test for 16 Years

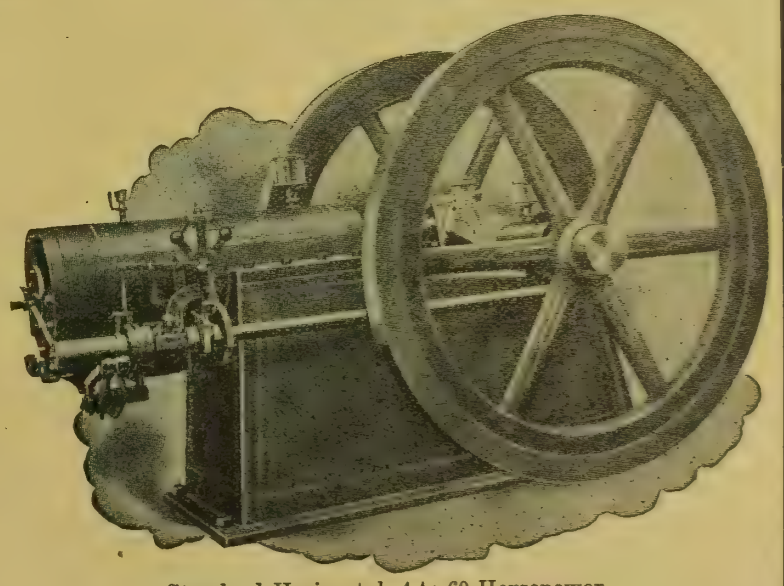
Gasoline or Distillate

Made by Columbus Machine Co.
Columbus, Ohio

3½-horse Vertical, $165, 1200 lbs.

Points of Excellence

Simplicity. Highest Efficiency.
All parts easy of access.
All wearing parts adjustable.
Long life of battery and electrodes.
Poppet Valves with removable seats.
Valves operated mechanically and not by suction.
All valves thoroughly water-jacketed.
No delicate parts to get out of order.
No unnecessary compression.
Closest regulation of speed.
Highest grade of material.
Best of workmanship.
Exhaust Valve opens against atmospheric pressure only.
Interior so located that fresh gas and air pass over the electrodes for each charge.
Change of speed while engine is running.
Can take up its load on any revolution without waiting to complete its cycle.
Explosion head cast solid with cylinder and no packing joint to blow out.



Standard Horizontal, 4 to 60 Horsepower.

Columbus Portable, 4 to 30 Horsepower.

We make a specialty of Installing Pumping Plants Complete.

Come in and see us or write.

THE object of the manufacturer has been to provide a simple engine, free from all complicated and trappy devices, which are constantly getting out of order, and are more difficult for the inexperienced user to understand and keep in adjustment.

AN ENGINE constricted of the very best material, equally adapted to use gas or gasoline.

AN ENGINE which does not compress or make an electric spark when not required, thus saving the exertion of the fly-wheels and prolonging the life of the battery and electrodes.

AN ENGINE so arranged that the speed can be changed while running.

AN ENGINE with the closest regulation, accomplished by an extremely sensitive governor, aided by heavy and properly proportioned fly-wheels, properly balanced and built in strict accordance with mechanical principles.

Setting Turkey.

I have a turkey hen just beginning to set on twelve of her own eggs. Will you please give me some information in regards to caring for her during the setting period? She and her eggs are in a covered box of straw. I have been told all eggs, chicken or turkey, should be placed on the ground, but knowing how contrary a turkey is, I am almost afraid to go near enough to feed them lest she will leave her nest.

When I found she was laying, and in this box, I never went near her, but left the eggs in the box as she would lay them. Since she commenced to set I have never bothered her in any way. Shall I continue to leave her and the eggs just where, and as they are?

How long does it take a turkey hen to hatch, and will you please tell me what to feed the babies for the first few weeks, should I be fortunate enough to get any.

Will it be advisable to keep them under cover or partly in the open?

I secured this hen and five babies last spring, but I lost two of them and I want better success this year, hence this letter to you.

I am thinking of purchasing a few pigeons for family use. How many and what breed would you suggest to supply squabs for a family of four? —W. L. L., Pasadena.

Turkeys are usually very good and close setters; you need not be afraid of her deserting her nest that she has chosen herself, and I would advise you to leave her where she is most likely she will hatch every egg, keep food, corn or rolled barley, near her, and also water for her to drink and spade up a place for her to dust herself every day.

Go near her every day and speak pleasantly to her and give her a little bit of bread or lettuce in your fingers so she will get to know you as her friend.

Turkey eggs take twenty-seven or twenty-eight days to incubate. I have written so recently in the Cultivator on how to raise turkeys that I will not repeat it here. Hard boiled eggs chopped finely shell and all, with equal amount of bread crumbs, and an onion every day are the principle food and always a pinch of coarse sand and one or two lettuce heads, and above all, do not over feed.

About squabs: Homers are the best, healthiest, and most profitable for family use. One pair of Homers will have from six to eight pair of squabs every year. How many do you want to eat?—Mrs. A. B.

Troubles of a Turkey Raiser.

I have been losing my little turkeys; I do not know the cause, tho' probably you could help me.

They die between three and four weeks old; their trouble seems to come on all at once, their wings droop and they shake as tho' they had the ague, at first; still they have a good appetite until they are past going. I usually find them this way in the morning and they die the same day.

I brought one in yesterday that would stand and cry and after crying would throw its head up and make a peculiar noise.

Last year I followed your direction in raising turkeys and did not lose any, so I can't understand this year what is the trouble. I thought yesterday that probably the gravel was not coarse enough, so changed it. Please reply as soon as convenient.—Mrs. O. S.

Little turkeys are at first quite delicate little things, and a small thing will affect them. If you are feeding and watering them according to my plan, we may know that the trouble is not in their food and must look elsewhere for the cause. Usually when turkeys droop their wings it is because their lungs are affected, they have taken cold.

Do you have fogs and damp grass for them to run in? Are they sleeping in a draught? Do they have the good, big wings of a turkey hen to cover them? Or how are they sheltered? Are they sleeping on damp ground? Have they lice? You see I do not know the circumstances, so find it very difficult to guess at the cause. A friend of mine had little turkeys that were dying with almost the same symptoms as yours. They were under olive trees that were irrigated, and the turkeys, from being in the shade and on damp ground, took cold and were dying just as yours are.

I do not know if you have fogs in your part of the country or heavy dews or if you have been irrigating. You will have to find out for yourself what is giving them cold, and remember that if they have lice they will take cold very quickly. The lice will give them a cold in the head and that goes easily to the lungs at the first chance.

A Nervous Trouble.

Will you please tell me what to do for my little turkeys? I am hatching them under chicken hens and commenced feeding them when they were 36 hours old with hard-boiled eggs and about the same quantity of bread crumbs moistened so as to swell, and chopped onion tops and whole heads of lettuce.

They have plenty of fresh water and I keep them in the brooder-house so as to keep them dry and warm. The hens are still with them as I have no heater in the brooder-house at present.

I have looked them over for lice but fail to find any.

I had 18 hatch out about a week ago; there are 13 left and they are nice and lively.

Those that died would commence by staggering, and shortly they would throw their heads back and go backwards cheeping as though in pain. One commenced before it had eaten anything, so I am at a loss to know what to do for them.

We have taken the Cultivator for 3 years, but am unable to find the above symptoms described in any of

For a Good, Practical Milking Machine see the O. J. Weber Co., 555-557 So. Los Angeles St., Los Angeles.

the papers at hand.—E. P. M., Pasadena.

The staggering back that you describe in your little turkeys is a nervous affection. It comes from either poisoning or from sunstroke, from indigestion, or from the eggs not being properly turned during incubation. I think your trouble comes from your keeping the little turkeys inside the brooder-house. They require to be out of doors in the fresh air much more than do chickens. Let them get out on clean, freshly-turned earth, or better still, on your lawn, keeping the mother chicken hen in a coop so that she will neither damage your lawn nor scratch and knock over the turkeys whilst they are too little and inexperienced to get out of her way.

Do not soak the bread. It is better to give it to them dry and let the gastric juice in their crop soak it up, and help digest it.

You say they have no lice. Better be sure of it, staggering is one symptom of lice. Get some buhach and rub it into the down on their head and neck, and watch for the lice to fall out in about five minutes.—Mrs. A. B.

IRRIGATION IN SAN DIEGO COUNTY.

Continued from Page 419

an aerating table and through a pressure filter, so that the quality is well-nigh perfect when delivered to the city.

4. Above one of the side tributaries of the Lower Otay, is the Upper Otay reservoir, which holds about one billion gallons and is now full. The water in the Lower Otay floods back to the base of the Upper.

Water could be taken from the latter by a separate pipe line to serve higher levels, but at present it is simply held in reserve and can at any time be run off into the Lower Otay.

When both the Barrett and Moreno dams are completed, the total capacity of the four reservoirs will be sufficient for every possible need of all the country, which can be served by them, and in that event no part of this state will have a better or more certain water supply than San Diego and its surrounding country.

At Bonita, in the Sweetwater valley, where the pipe lines of the Sweetwater and Spreckels systems cross, arrangements are made by which they can be joined so that the Sweetwater system could in time of need be supplemented by that of the Southern California International Water Company.—R. C. Allen, Bonita.

PRE-COOLED ORANGES.

On Wednesday, April 17th a Cultivator representative visited Uncle Sam's experimental plant for the pre-cooling of packed cars of fruit, situated on the river bank in the city of Los Angeles, being one of several in Southern California in charge of Mr. G. Harold Powell, whose name is familiar to all our readers.

The investigations of the United States Department of Agriculture into the cause of decay in oranges in transit are on a much larger and broader scale this year than in former years. They include:

1. Experiments in about thirty-five packing-houses in all parts of the citrus belt to bring out the effect of handling the fruit in different ways. Some unbrushed, dry brushed and washed fruit, mechanically and commercially packed fruit, injured fruit, is left in the house two weeks, then examined in the presence of growers, shippers and packers. Nearly 100 tests of this kind have been made and the results show that the fruit as it comes from the tree seldom decays and that the allowance of rot increases in proportion to the amount of handling the fruit receives unbrushed sound fruit decays least, brushing raises it to a greater or less degree washing increases it still more, and the mechanically injured fruit rots the most.

2. The shipment of sound brushed and washed fruit, commercially packed fruit and mechanically injured fruit at different lengths of time after packing, and shipped under ventilation, icing, and pre-cooling, followed by icing. About 100 cars have been shipped to date and 50 more will be forwarded. The results are as clear cut as a problem in geometry, the decay increasing in proportion to the amount of handling the fruit receives and the time elapsing between packing and shipping. It also varies directly with the temperature; the fruit decaying least in the pre-cooled cars.

3. The determination of the keeping quality of oranges handled in different ways and shipped under the three methods after the fruit arrives in the eastern market.

The government representatives have been working on the breeding of deciduous and citrus fruits for several years and are now cooling several cars a week in warehouses at Pasadena and at Riverside, and with an air circulating system at the Los Angeles Ice and Cold Storage Company's plant at 7thst. and Santa Fe tracks.

This Los Angeles plant was constructed by Mr. S. J. Dennis, an expert in refrigeration on the Department staff, for the purpose of securing technical data on the practicability of cooling oranges in cars by forcing cold air through the car. The plant consists of a 30-inch insulated duct leading from an ammonia coil room to one end of the car, a similar duct returning from the opposite end of the car to the coil room, two large fans to force the air through and return it, and a series of valves, which make it possible to circulate the air through the car in either direction. Mr. Dennis is securing data on the amount of refrigeration required, the temperature of the air entering and leaving the car, the volume and rapidity of circulation and the temperature of the air and of the fruit at different parts of the car. At the end of the season, data will have been secured that will determine the value or impracticability of this system of refrigeration.

Mr. Powell has associated with him a half-dozen of the ablest scientists in the country, Messrs. Stubenrauch, Tenny, Eustace, Hosford and White, experts in fruit storage and transportation and Mr. S. J. Dennis, a refrigerator engineer.

THE STOVER STILL FORGES AHEAD.

Now that the season for artificial irrigation is again approaching and the quiet country solitude will soon be broken by the muffled reports of the gas-engine, it is well for the farmer to turn his attention to the merits of these same gas-engines so that when the rains are really over and the ground begins to bake with the summer heat, he will not be found as were the foolish virgins of Scripture, with their lamps untrimmed at the eleventh hour.

Anticipating the rapid approach of summer, Livingston & Lee, Southern California agents for The Stover Gas Engine, report that they have two carloads of engines arriving next week which will put them in a position to furnish anything from 2 H. P. to 40 H. P. at once.

The rapid strides, even through the winter months, of this simple engine have been so very satisfactory that the firm has secured additional capital to further push the sale of The Stover and this summer expects to touch fields they have not done before.

They have so enlarged their quarters that in addition to retaining their old sales-room and office on N. Main street, they have established a warehouse and yard at 1310 San Fernando street, where they intend to install machinery to make their own pump fittings, build pump frames and do all work in connection with installing up-to-date pumping plants.

The main points of superiority of The Stover are its simplicity and its great power. Its speed regulating device also appeals to many.

Take it all and all there is no engine on the market today that is better calculated to meet the requirements of the farmer than The Stover and it is well worth any farmer's time to pay a call on Livingston & Lee at 953 N. Main street, Los Angeles, and see one in operation.

USED CAUSTIC BALSAM

Lovelock, Nev., Nov. 15, 1905.
The Lawerence-Williams Co., Cleveland, O.:

Kindly send me your descriptive circulars, describing GOMBAULT'S CAUSTIC BALSAM. Have used the Balsam with much success, by following the directions coming with each bottle. G. S. WEBB.

Poultry Supplies and Seeds of All Kinds

Pacific Incubator Company

has opened a store in Los Angeles for the sale of

Incubators Brooders

and a full line of

POULTRY SUPPLIES

New, fresh stock at the lowest prices. Come and see us or send in your orders.

Before buying you should see the

"Business" Incubator

Capacity 100 eggs, $10 delivered. Hot water, copper boiler, nursery, Best Sheer Regulator; everything the best. No mahogany, no frills, no furbelows. Also,

"Business" Brooder at $7.00

Not a box, but genuine brooder.

The "Business" is built for business, and it does the business every time. Come and see it.

707 So. Spring St., Los Angeles

The Only Proof of an

INCUBATOR IS WHAT IT WILL DO

The wide-spread success of Glendale Incubators and Brooders is due to the fact that these machines actually overcome the objections of older makes. They are a distinct improvement. They give so much better results, require so little attention, and do this work so perfectly that no poultry man who stops and figures out the matter on a dollar and cent basis can afford to use any other kind.

If you will investigate, if you will ask your friends, if you will come and see the points of difference, the improvements, you will get in line and use Glendales.

The manufacturers give a positive guarantee of money back if not satisfactory.

One big poultry dealer, who is recognized for his keen knowledge of the business says: "I have tried every first-class incubator and brooder on the market, and the Glendales certainly are a revelation to me. They deserve the support of every poultry man for they are certainly built on honor and do their work well."

The 120-egg size, $22; 240-egg size, $32; 360-egg size, $42; 500-egg size, $52.

We want you to attend a free demonstration now being conducted. If this is not convenient, write for catalogue.

Johnson & Musser Seed Co.

Building the Irrigation Ditch

Having decided upon the point of diversion and located the ditch line, the farmer is ready to build the ditch. Experience in making drain ditches will help in this.

But there is this difference: Drain ditches must be kept in the ground as deep as practicable, while irrigation ditches must be kept as near the surface as may be, in order that the water can be easily taken out. The line of the ditch should first be marked by a furrow. To do this, let one man guide the team, walking between the heads of the horses, holding a bit in each hand, while another holds the plow.

If the surface of the ground is such as to permit a wagon to pass along the line, the plow may be attached to the rear axle, the driver directing the team from the seat of the wagon. The furrow should be turned to the lower side of the ditch. If the surface of the ground is comparatively level across the line of the ditch, it is not necessary to follow the stakes closely in the bends. The ditch will be better for being straightened a little, which may be done by going above the stakes that locate the bends nearest the stream and below the stakes farthest away.

If the ground slopes very much across the ditch line the stakes must be followed closely. After the line is marked, two or three furrows are plowed, all being turned to the lower side. A farm ditch can be made almost wholly with an ordinary plow by going over the line a number of times. The loose earth in the bottom of the ditch may be removed with a scraper or shovels.

A small stream can be easily diverted into a ditch, if it is running in a shallow bed, by a cross-stream dam of posts and plank, of posts and brush, of brush and rock or cobbles, etc. Such structures are not usually water-tight, but they will raise the water to the level of outflow into the ditch which is to carry it to the land to be irrigated or to the reservoir from which it is to be distributed. A better dam, either of masonry or of earth, made water-tight by a puddle bar of clay, may last for a long time in a small stream if adequate arrangements are made for the passage of waste and flood water.

Raising a small stream in a deep bed requires a dam of greater strength. In such cases it is safer to make the dam of timber or masonary arching upstream, bedded well into the banks, and puddled well above with clay, to prevent leakage, which would soon undermine and carry down an otherwise good structure. Such a dam will cause the bed of the stream above it to fill with sediment, which will reduce the direct pressure. The beginner, however, will do well to err on the safe side, if at all, and make his dam twice as strong as might seem on first thought to be necessary.

In a wider stream in a shallow bed enough water can often be diverted by a wing dam, starting just below the head of the ditch and running obliquely up the stream toward its center. Such a dam can be easily constructed of posts and brush, or of any coarse, heavy material which is ready at hand or most cheaply secured. It raises part of the water sufficiently for outflow into a ditch and is not enough of an obstruction to be torn out in high water, or, if the dam is partly destroyed, it can be cheaply replaced.

Courtesy Hawley, King & Co., Los Angeles

Twentieth Century Grader

Doing work of plow, digging up sod preparing to make gutter. It will establish a graded, curved form of road so that it will shed water easily

IRRIGATION POINTERS.

Summer irrigation promotes a root system near the surface and proper development of fruit on trees with such a system of feeders requires irrigation. In other words, an orchard once irrigated will suffer more from drought than one never irrigated.

In low places, especially where the ground water is too near the surface, irrigation has had bad effects. Fruits have not such good flavor, grapes are late, and sometimes trees are killed.

Orchards have been killed outright by constant irrigation by Chinamen growing vegetables among the trees.

The Home of a Plant-Lover

PARTLY HIDDEN by wide-spreading pepper trees on beautiful Villa street, Pasadena, is the comfortable and cozy home of a plant-lover who, in a quiet way, has done much to raise the standard of horticulture in California. New plants have been introduced and acclimated, then distributed. Still more, where nature had failed to round out to its fullest and give what he knew could be secured by meeting nature on her own ground, there he bent his energies to secure the highest nature had to give.

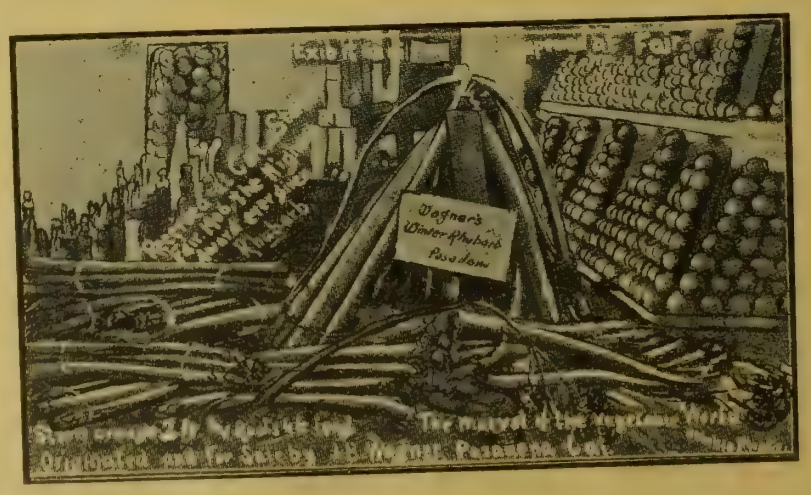
The home interior shows by its tasty arrangement the refinement, which reigns there. Music-lovers as well as plant-lovers, usually demand refined surroundings. These are all seen in this home—the home of J. B. Wagner, the "Rhubarb King" of California.

We do not know that he is the largest producer in a marketing way, but in the production of better varieties and in creating greater wealth-producers he is the peer of any who have had to do with rhubarb.

In a quiet way this has been known to many of Mr. Wagner' friends, but only recently has the public been made aware of the effective work which is being done in the little experimental plot at the base of the Sierra Madres.

An exhibit of this rhubarb was made at State Fair at Sacramento, and attracted large numbers of people to the booth, where Mr. Wagner gave information to all inquirers. Among those inquirers was the party of Governor Pardee, who expressed great satisfaction in the fact that such rhubarb could be produced in this State, which has a reputation of being a poor producer of rhubarb on account of its arid condition. This large exhibit, a photograph of which appears on this page, was made up entirely from these first plants which Mr. Wagner secured from the seed of the Crimson Winter Rhubarb, hydridized with the Lorenzo. At the display made at the fair, the size and the length of the stalks was not the only form in which it was exhibited; for Mr. Wagner also showed the quality of sauce made from it to be the equal in every way to the Crimson Winter. We say the equal in every way, though some prefer the coloring of Crimson Winter to that of this hybrid; for it is not quite as deep a red as its parent. In flavor and in lack of any "rag" it is fully the equal of the Crimson Winter.

The flavorable comment won at the fair, together with Mr. Wagner's own knowledge of the worth of this plant, might be thought to settle at once upon it as worthy of the widest propagation and distribution; but there is one other factor to be determined before he will consent to spreading it broadcast over the land. This factor is: "Will its admirable qualities be conveyed to its offspring—will the seed come true?" This experiment will require some time to settle to Mr. Wagner's satisfaction. From the limited experiments which he has tried, he is most hopeful that it will have this quality to the extent of the Crimson Winer; and if it does, it will certainly become at once a favorite to a far greater extent than has the Crimson Winter. For with the admirable qualities of size and flavor is the added advantage of less seed stalks than the Crimson Winter; consequently more of its vitality goes to the "fruit" or edible stalks.



Mr. Wagner has such unbounded faith in his rhubarb that he has been sending out stock to grow on shares. That is, those who had any doubt about the profit end of the business could get stock free of charge for planting on an agreement to give Mr. Wagner a share of the first, second or third year's crop, or all three as as agreed upon, for Mr. Wagner has backed up his faith and convictions regarding this wonderful rhubarb by allowing a large number of growers to take stock on practically their own terms.

So many have availed themselves of this generous offer that Mr. Wagner announces that his stock is almost sold out, and that he has only reserved enough high-class roots to meet the present season's demands. So popular has this rhubarb become that this necessary stock for a trade supply is very large and if any remains unsold it will be planted on the home grounds.

Those anticipating planting this season, and everybody should do so who has not, will do well to get their orders in at once, for now is just the favorable time to plant to get those surprising results for next winter that has marked the growing of this rhubarb wherever it has been introduced.

Many experiments have been made with growing this high-class rhubarb to find out just the best time to plant for the greatest possible success. Mr. Wagner has, in his usual thorough manner, carefully noted down every planting made for several years and has found that the months of April and May are the best to insure heavy crops next winter, beginning just as all fresh fruit and vegetables are going out of the market and an active demand springs up for something fresh, succulent and appetizing. Thus, it will be seen, that the time to order is now.

Mr. Wagner is worthy of highest commendation for his indefatigable research. May he secure highest success.

MEASUREMENTS OF SMALL STREAMS.

Before discussing sources of supply it is important to cite a method by which the quantity of water available in a small brook, outflow from a large spring, or discharge from a drainage system may be easily ascertained.

Without an estimate of the supply, reservoir building or the determination of the area which can be irrigated is merely guess work. Recourse to the miner's method of measurement is best for such sources as will frequently be drawn upon for the farm supply. It consists in causing the water to flow through an opening, the capacity of which is known, and which is readily capable of adjustment to the flow in any case.

A simple form of this device is a board 1 inch thick, 12 inches wide and about 8 feet long. The opening is 1 inch wide and 50 inches long, and the distance from the top of the board to the center of the opening is exactly 4 inches on the upstream side. On the downstream side the opening is beveled so that the hole presents sharp edges to the stream. A sliding board is hung upon the top of the first board with a strip screwed along its upper edge, this sliding board being wide enough to cover the opening on the upstream side. In the slot there is a closely-fitting block made to slide on the beveled edges, and fastened by a screw to the sliding board. It is obvious, then, that when the sliding board is moved backward or forward, by means of its end, which is extended for a handle, the block moves in the slot and determines the length of the opening.

In operation the board is placed in the stream so as to dam the flow completely, and the sliding board is moved backward or forward until the water is all passing through the slot, the water being kept up to the top of the board, or 4 inches above the center of the opening. The length of the opening measures the number of miners' inches of water flowing through. If the flow is too great to pass through the opening 1 inch wide the opening may be made wider, the water still to be kept 4 inches above the center of the opening. The laws of several states provide that in devices for measuring water for sale by the miner's inch the opening shall be 6 inches high, and shall be provided with a slide. The number of miners' inches then discharged is equal to the number of square inches in the opening.

The assumption made that the discharge is proportional to the size of the opening is not true, but the error in measuring small quantities is not great enough to be taken into consideration. By converting the results of measurements in miners' inches to gallons, cubic feet, or some other familiar unit, it may be determined how long it will take the stream to fill a reservoir or cover a given field with the necessary depth of water. This unit is readily convertible into cubic feet or gallons or acre-inches of water, according to the time the water flows.

SAN JOAQUIN ARTESIAN BELT.

Where so many natural advantages are to be found coupled with such abundant fertility of soil, it is not strange that means should be sought to supply any deficiency of moisture that might occur from time to time and thus to render crop production a matter of inevitable certainty from year to year.

But nature has been lavish in her gifts to this region. This valley is situated in the greatest artesian basin known. Just underneath the thousands of square miles of land comprising this valley lies a sheet of water under such a head of pressure that when pierced by the drill of the engineer, a fountain of water rushes out with such force that it rivals the mechanical possibilities of a huge Corliss engine and with sufficient volume to create and sustain lakes and flowing streams.

Too much water with poor drainage will sour the soil and cause gum disease and yellow leaf.

$3.50 WILL BRING YOU THIS

A REVOLVER EVERY FARMER SHOULD OWN

Hopkins & Allen "WILD WEST" REVOLVER

POST-PAID BY MAIL

32 or 38 Calibre

6 Inch Blued Steel Barrel

Write for our Big New "Gun Guide and Catalogue" for 1907. It's free and the best and most interesting Firearm Catalogue published in America. Offers best prices.

HERE'S A REVOLVER THAT OUGHT TO BE IN THE POSSESSION OF EVERY FARMER IN THE COUNTRY. It is especially designed for the farmers use—long range shooting and extra thorough protection. With it you can get at the night prowler in barnyard or chicken lot without coming to close quarters with him, and the blued barrels keep the sights clear in the moonlight giving you double protection against the foe.

DESCRIPTION: This revolver is specially constructed for farmers use, of high-grade material throughout, **and is warranted to give extra good satisfaction. Barrel and cylinder** are made of best blued revolver steel, drop forged, with our popular improved quick twist rifling, which **increases velocity and improves trajectory. Cylinder** is supplied with ratchet stop and counter-sunk pinion giving rapidity of action and extraordinary accuracy. **Frame** is made of Blued Steel and all lock work of high-grade spring steel. **Hammer and Trigger** are made of fine drop forged steel, **case hardened**; hammer rebounds after firing—never resting on cartridge except at the instant of discharge. Revolver is **Double Action,** self-cocking with hard, checkered rubber handle, pistol shape, which fills the hand and gives an excellent grip. 32 Calibre, 6 shots, 38 Calibre, 5 shots. ALL IN ALL, THIS REVOLVER IS EXTRA HIGH-GRADE FOR THE PRICE, AND FOR FARMERS USE IS SUPERIOR TO MANY OTHER REVOLVERS COSTING TWICE THE MONEY.

IF YOU SHOULD NOT FIND THE "WILD WEST" REVOLVER AT NEAREST HARDWARE STORE SEND $3.50 DIRECT TO US, AND WE WILL FORWARD IT AT ONCE, POST-PAID BY MAIL WITH AN ABSOLUTE GUARANTEE OF SATISFACTION, OR IMMEDIATE REFUND OF MONEY. Same Revolver, 4½ in. barrel, $3.25, 2½ in. barrel, $3.00. Mention Calibre wanted when ordering.—Write us at once.

THE HOPKINS & ALLEN ARMS CO. 121 FRANKLIN ST., NORWICH, CONN., U. S. A.

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

POMONA MANUFACTURING COMPANY

Corner of Bertie and Gibbs Streets POMONA, CAL

LINERS

DUCKS.

INDIAN RUNNER DUCKS—A WORLD beater for producing Eggs. Pure strain. $1.00 for 13; $5.00 for 100. Black Langshans, Prize Pen. $2.00 for 13. F. M. BENDER, Corona, California.

BUFF ORPINGTON DUCKS—248 EGGS IN 145 days from our two imported ducks. Eggs $3 per doz. Nothing better to raise. GOODACRE BROS., Compton, Cal.

PEKIN DUCKS—STOCK DUCKS $1.50 each; young at $1 each; 2 extra drakes $3 each; all our Cup Winning Strain. GOODACRE BROS., Compton, Cal.

H. R. CAMPBELL

BOX O PETALUMA, CAL.

Irrigation without cultivation—and that in the most thorough manner—is productive of injurious results, and where irrigation has not given satisfactory results it will be found that it was not followed by the proper cultivation.

Fruit trees are injured by subirrigation without drainage for surplus water. Standing water is destructive to the roots.

Trees can be injured, especially on roots which do not like too much water and on soils where the subdrainage is defective.

The Produce Markets

Los Angeles Markets

LOS ANGELES, April 17, 1907.

Quietness reigned on the Produce Market today. There seemed to be little pressure either to buy or sell staple commodities, with the exception of eggs; butter market is steady; potato arrivals heavy; prices remain firm; green vegetables still sell well.

Butter.

The butter market is steady at the new quotations. Butter prices are expected to remain as now quoted for some time to come, as dealers can store the surplus at present prices, and yet this surplus is not sufficiently great to warrant a further decline. There is little possibility of an advance this late in the season unless there is an unexpected heavy storm in the North and supplies are again curtailed.

Valley Creamery	47½

Heifers	4½
Calves per lb.	5
Sheep, ewes, per head	5.00@5.25
Lambs per head	6.50
Wethers	5.50

Potatoes

Potato arrivals yesterday were large, but the market seems firm. No fancy stock is offered under $1.65 in a jobbing way, and from this figure prices to $1.85 are asked for some varieties.

Sweets, Yellow, per sack	5.00
Sweet, White per sack	4.75
Colorado	2.05
Minnesota	2.00
Early Rose, Northern	2.50
Early Rose, Eastern,	2.25
Oregon,	2.25

Vegetables

Notwithstanding a general over supply in nearly every variety of fresh green vegetables, the market was fairly well cleaned up by noon. The over abundance of green stuff caused a material reduction in prices, and it was due to the wholesale price-cutting that the goods were cleaned up. The most noticeable declines were sugar peas to 2@3 per pound, lettuce to 25c per crate, cabbage to 75c@$1 per sack, turnips to 10@20c per dozen bunches and Mexican tomatoes to $1.25@$1.50 per four-basket crate.

Asparagus, lb	10@14

SICILY LEMON SALES.

NEW YORK, April 16.—Seventeen thousand boxes of Scilly lemons, ex steamer Ida, were sold today. The market is from 15c to 20c higher, with a strong preference shown for 360s, although 300s were also eagerly taken, denoting urgent orders. There were no periods of weakness. Fancy 300s sold for $4.00 to $4.40; seconds, $3.75 to $4.10. Fancy 360s sold for $4.50 to $4.80; seconds, $4.10 to $4.50. Fancy 500s sold from $5.10 to $6.05.

The next sale will be Friday—six and possibly sixteen thousand boxes.

CALIFORNIA CITRUS SHIPMENTS.

LOS ANGELES, April 16.—Monday, April 15: Oranges, 182 carloads; lemons, 10 carloads. Total to date this season, 14,422 carloads, of which 1416 carloads are lemons. Total to same date last season, 16,469 carloads, of which 1641 were lemons.

Cream Separators, all sizes, all prices. See O. J. Weber Co., 555-557 So. Los Angeles St., Los Angeles.

SMALL IRRIGATION DITCHES.

When a farmer enters a new country where irrigation is necessary he must determine (1) how he may best deliver water to his land, and (2) wnat crops are adapted to the soil and for local uses.

Everything with him is tentative. Unless he is fortified by an income outside of that obtained from his farm, the first few years he has a struggle for existence. That the pioneer is often overcome in this unequal fight is evidenced by many deserted homes and unfinished irrigation works.

Owing to his inexperience in irrigation, he may lose his crops by not using the proper volume of water or by using it at the wrong time. One failure often means the abandonment of everything and a retreat to a region where conditions seem more favorable.

In a new country where the rainfall is ample for the growth of crops serious obstacles must be overcome before returns are received for the labor expended. If, in addition to these difficulties, water must be brought to the land for irrigation and domestic purposes, the problems become much more complicated, and correspondingly greater credit is due when success rewards the attempt.

To the Eastern farmer, whose cultivated lands are rolling and broken, the problem of spreading water over the surface of the ground from ditches has some serious phases. Often the stream passing his farm is bordered by steep bluffs, and its fall seldom exceeds 3 to 4 feet per mile. In his judgment the cost of raising water from such a source in sufficient quantities for irrigation would not be justified by the slight increase in yields or the saving of an occasional crop.

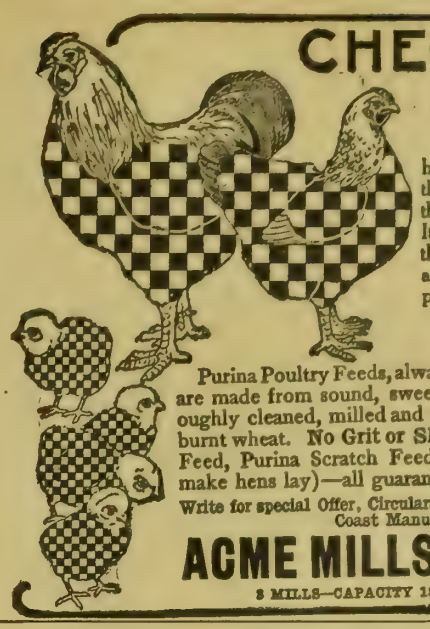
The Western irrigator would arrive at the same conclusion if he had to deal with similar conditions. His agricultural land is nearly always smooth, and usually has a gentle slope with and toward some natural drainage channel, and would bear no crops without irrigation. The stream from which he proposes to draw his supply of water has a large fall, so that a ditch taken from it with a moderate grade can recede rapidly, and hence cover a large area in a short distance. A combination of these features makes it possible for individuals to construct irrigation works on the smaller streams.

THE MOST EFFICIENT REMEDY OF ITS KIND.

COVINA, Cal., July 17, 1905.—The Lawerence-Williams Co., Cleveland, O.:

Please send me your pictures of Famous Horses. I have carried GOMBAULT'S CAUSTIC BALSAM in stock constantly for the last twelve years, and recommend it as the most efficient remedy of its kind on the market. It should always be kept in every stable. C. F. CLAPP.

The Johnson & Musser Seed Co. received a car load of seed corn this week which has been long delayed by the freight blockade.



CHECKERBOARD CHICKENS

Why are you raising Chickens? For your health or to make money? If to make money then you must **feed right.** Mixing a few things together doesn't make a Poultry Feed. It is a scientific proposition and requires a thoroughly equipped mill to grind and clean and blend grains and seeds in just the right proportion for baby chicks or laying hens.

The Purina Checkerboard Bag

Purina Poultry Feeds, always in checkerboard bags, are made from sound, sweet grains and seeds thoroughly cleaned, milled and screened. No smutty or burnt wheat. **No Grit or Shell.** Purina Baby Chick Feed, Purina Scratch Feed, Purina Egg Food (to make hens lay)—all guaranteed.

BEFORE THE RAIN.

We knew it would rain, for all the morn
A spirit on splendor ropes of mist
Was lowering its golden buckets down
Into the vapory amethyst.

Of marshes and swamps and dismal fens—
Scooping the dew that lay in the flowers,
Dipping the jewels out of the sea.
To sprinkle them over the land in showers

We knew it would rain, for the poplars showed
The white of their leaves; the amber grain
Shrunk in the wind; and the lightning now
Is tangled in tremulous skeins of rain.

After The Rain.

The rain has ceased, and in my room
The sunshine pours an airy flood;
And on the church's dizzy vane
The ancient Cross is bathed in blood.

From out the dripping ivy-leaves,
Antiquely carven, gray and high,
A dormer, facing westward, looks
Upon the village like an eye.

And now it glimmers in the sun,
A square of gold, a disk, a speck;
And in the belfry sits a dove
With purple ripples on her neck.—
—Thomas Bailey Aldrich.

IMPRESSIONS OF NIAGARA.

WE WERE at the foot of the American fall. I could see an immense torrent of water tearing headlong down from some great height, but had no idea of shape, or situation, or anything but vague immensity.

When I was seated in the little ferry-boat, and was crossing the swollen river immediately before both cataracts, I began to feel what it was; but I was in a manner stunned, and unable to comprehend the vastness of the scene. It was not until I came on Table Rock, and looked—Great Heaven, on what a fall of bright, green water!—that it came upon me in its full might and majesty. Then, when I felt how near to my Creator I was standing, the first effect and the enduring one—instant and lasting—of the tremendous spectacle, was peace. Peace of mind, tranquility, calm recollections of the dead, great thoughts of eternal rest and happiness; nothing of gloom or terror. Niagara was at once stamped upon my heart, an image of beauty; to remain there, changeless and indelible, until its pulses cease to beat forever.

Oh, how the strife and trouble of daily life receded from my view and lessened in the distance, during the memorable days we passed on that enchanted ground! What voices spoke from out the thundering water; what faces, faded from earth, looked out upon me from its gleaming depths; what heavenly promise glistened in those angels' tears, the drops of many hues, that showered around, and twined themselves about the gorgeous arches which the changing rainbows made!

I never stirred in all that time from the Canadian side, whither I had gone at first. I never crossed the river again; for I knew there were people on the other shore, and in such a place it is natural to shun strange company.

To wander to and fro all day, and see the cataracts from all points of view; to stand upon the edge of the great Horseshoe Fall, marking the hurried water gathering strength as it approached the verge, yet seeming, too, to pause before it shot into the gulf below; to gaze from the river's level up at the torrent as it came streaming down; to climb the neighboring heights and watch it through the trees, and see the wreathing water in the rapids hurrying on to take its fearful plunge; to linger in the shadow of the solemn rocks three miles below, watching the river, as, stirred by no visible cause, it heaved and eddied and awoke the echoes, being troubled yet, far down beneath the surface, by its giant leap; to have Niagara before me, lighted by the sun and by the moon, red in the day's decline, and gray as evening slowly fell upon it; to look upon it every day, and wake up in the night and hear its ceaseless voice,—this was enough.

I think in every quiet season now still do those waters roll and leap and roar and tumble, all day long; still are the rainbows spanning them, hundred feet below. Still, when the sun is on them, do they shine and glow like molten gold. Still, when the day is gloomy, do they fall like snow, or seem to crumble away like the front of a great chalk-cliff, or roll down the rock like dense white smoke. But always does the mighty stream appear to die as it comes down, and always from its unfathomable grave arises that tremendous ghost of spray and mist which is never laid,—which has haunted this place with the same dread solemnity since darkness brooded on the deep, and that first flood before the deluge—light—came rushing on creation at the word of God.—Charles Dickens.

THE MULE WITH THE GO.

Bowed with the ignominy
Of the Kentuckian's inegenuity
He stands and gazes into space;
No pride of ancestry in his mien,
No hope of posterity in his face.
Upon his back the indolent negro
Rides to and from the plow,
The saplings 'round the country church
Are familiar with his bray.
Who made him dead to the bull-whip crack
And the plowline's sting?

Who toughened his hide to that extent
He winces not at the "yaller-jacket's" caress?
Is this the thing Kentucky gave man
To take the place of the patient ox,
To tighten the traces of industry,
And kick the vanities out of civilization?
Slave to the log cart and the plow,
What consolation to him
Is the philosophy of induction
And the electric trolly car?
The rift of dawn usually finds him
Chewing a cud of musty hay,
Waiting patiently Time's tragedy
To be re-enacted the coming day.
Thumped, lambasted and "cussed at"
He enters no cry of protest,
Therefore is not guilty of prophesy;
But bides, uncomplainingly, the time
When his supple and unerring heels
Shall kick his tormentor into eternity.

DECORATION OF THE FARM HOME.

The simple training of ivy over a mantel allowing its branches to drop to the floor is beautiful; if there is a bay window, a nest of ferns out of which a calla or a single plant towers above the green, is very effective.

There must be an entire lack of formality, especially at a quiet home gathering where sociability and hospitality are at their best. The simple, unstudied effect will be in perfect harmony with the occasion.

THE STREAM OF LIFE.

Life bears us on like the current of a mighty river. Our boat at first glides down the narrow channel, through the playful murmurings of the little brook and the windings of its grassy borders. The trees shed their blossoms over our young heads; offer themselves to our young hands; we are happy in hope, and we grasp eagerly at the beauties around us;—but the stream hurries on, and still our hands are empty.

Our course in youth and manhood is along a wider and deeper flood, amid objects more striking and magnificent. We are animated by the moving pictures of enjoyment and industry passing before us; we are excited by some short-lived success, or depressed and made miserable by some equally short-lived disappointment. But our energy and our depression are both in vain. The stream bears us on, and our joys and griefs are alike left behind us.

We may be shipwrecked—we cannot be delayed; whether rough or smooth, the river hastens to its home, till the

roar of the ocean is in our ears, and the tossing of the waves is beneath our feet, and the land lessens from our eyes, and the floods are lifted up around us, and we take our leave of earth and its inhabitants, until of our further voyage there is no witness save the Infinite and Eternal.—Reginald Heber.

THE MIGHTY WATERS.

In itself the ocean panorama is very grand. It would be hard to exaggerate the beauty of both sea and sky, especially in and near the tropics. The sky near the horizon was of pale blue, and often the clouds all around the sea line of a light pink tint, and the sea near the ship like an amethyst or the wing of some tropical bird. In those rare times when the sea was calm, the motion of the ship made it flow in large sheets as of some oily liquid; or, again, like the blue steel of some polished cuirass.

What is there more sublime than the trackless, all-surrounding, unfathomable sea? What is there more peacefully sublime than the calm, gently-heaving, silent sea? What is there more terribly sublime than the angry, dashing, foaming sea? Power—resistless, overwhelming power—is its attribute and its expression, whether in the careless, conscious grandeur of its deep rest, or the wild tumult of its excited wrath.

SEVEN AGES OF MEN.

All the world's a stage,
And all the men and women merely players;
They have their exits and their entrances
And one man in his time plays many parts,
His acts being seven ages. At first the infant,
Mewling and puking in the nurse's arms,
Then the whining schoolboy, with his satchel
And shining morning face, creeping like snail
Unwillingly to school. And then the lover,
Sighing like furnace, with a woeful ballad
Made to his mistress' eyebrow. Then a soldier,
Full of strange oaths, and bearded like the pard,
Jealous in honor, sudden and quick in quarrel,
Seeking the bubble reputation
Even in the cannon's mouth. And then the justice
In fair round belly, with good capon lined,
With eyes severe and beard of formal cut,
Full of wise saws and modern instances—
And so he plays his part. The sixth age shifts
Into the lean and slippered Pantaloon,
With spectacles on nose and pouch on side,
His youthful hose, well saved, a world too wide
For his shrunk shank; and his big manly voice,
Turning again toward childish treble, pipes
And whistles in its sound. Last scene of all,
That ends this strange eventful history,
Is second childishness and mere oblivion—
Sans teeth, sans eyes, sans taste, sans everything.

—Shakespeare.

THE GULF STREAM.

There is a river in the ocean. In the severest droughts it never fails, and in the mightiest floods it never overflows. Its bank and its bottoms are of cold water, while its current is of warm. The Gulf of Mexico is its fountain, and its mouth is the Arctic seas. It is the Gulf Stream. There is in the world no other such majestic flow of waters. Its current is more rapid than the Mississippi or the Amazon, and its volume more than a thousand times greater.

The very best effect of flowers for the little social gatherings of the farm home is secured by the simplest possible arrangements.

No Nitrate of Soda used — Nitrate of Soda was used here

Giant Hay Crops

An average increase of 2775 pounds per acre of field-cured hay was shown in 11 actual tests where Nitrate of Soda was used. Tests were made from Nova Scotia to Missouri, and only 100 pounds of

NITRATE OF SODA

was used per acre. Compare increase with cost of this great fertilizer. Compare fields shown in above actual reproduced photograph. Nitrate of Soda is best and cheapest Nitrogenous fertilizer with which to furnish Nitrogen to plants.

Test It for Yourself Entirely Free Let us send sufficient Nitrate of Soda for you to try, asking only that you use according to our directions, and let us know the result. To the twenty-five farmers who get the best results, we offer, as a prize, Prof. Voorhees' most valuable book on fertilizers, their composition, and how to use for different crops. Handsomely bound, 327 pages. Apply at once for Nitrate of Soda, *as this offer is necessarily limited.* Valuable illustrated books of useful information, will be sent free to farmers while the present edition lasts, if paper is mentioned in which this advertisement is seen. *Send name and complete address on post card.*

WILLIAM S. MYERS, Director, John Street and 71 Nassau, New York

What do Your Crops Cost?

IT IS not what your crop brings on the market so much as what it costs you to raise it that counts in farming.

If you are farming on high-priced land under the most trying difficulties—if your soil has begun to fail, and your crops are not so large as they used to be—if it takes so much high-priced help to produce and harvest your crops that there is no profit left, you are not making much money farming.

Why don't you sell out at the high prices you can now realize and invest your cash in land where you can get five or ten times as many acres for the money, of better, newer soil than that you own at present?

When you bought the farm you now own, it was cheap—the rise in land values made you rich. Why not do that same thing over again?

In Southern Alberta, Canada, is to be found as rich land as there is anywhere. It will raise anything that your land will raise, with possibly one or two exceptions. It is the greatest live stock country on earth, and the markets are just as good as the markets you now patronize.

In this new country you can raise crops at a small percentage of what it now costs you to raise them, because climatic conditions are such that one man can attend as many acres as in your country, and each acre will produce from two to four times the quantity one of your acres will produce if you are farming without irrigation.

On the vast irrigated tracts of Alberta you can find a farm that will just suit you, and you can rest assured that if you farm it fifty years you will never have a crop failure. No waiting for rain—no chance at all to take—just a certain, sure crop every time you put seed in the ground, and a bigger crop than you can hope to raise on unirrigated ground.

If you are interested in very fertile land, at low prices, with a certain harvest every year, we can sell it to you on terms that are so easy there is no excuse for any man being without a farm.

Write us for full particulars, and let us tell you how to see Alberta and this land at very little cost for the trip—let us tell you how to become independent in two years.

Losses by Evaporation

Bulletin 177 of the Office of Experiment Stations, United States Department of Agriculture, just issued, gives the result of experiments covering several years, performed in co-operation with the State of California, for the purpose of estimating the losses of water by evaporation from irrigated fields and determining the effect of different methods of applying water and of cultivating fields in checking these losses. This work was done in California under the supervision of Samuel Fortier, under the direction of Elwood Mead, Chief of Irrigation and Drainage Investigations.

Water Costly.

In Southern California water has a very high value and the supply is limited, making it important to economize in every way possible. Thousands of dollars have been spent in lining ditches with cement and in putting in underground pipes for carrying water to the points where it is put upon the land, so that losses in transporting water, which in open earth channels often equal one-half the supply at the head of a ditch system, have been largely eliminated.

It has been realized that there are still large losses occurring when the water is applied to the soil, but there has been little or no knowledge of the extent of these losses or the exact effect of different methods adopted for checking them. This work of Professor Fortier's is an attempt to measure both by means of experiments with soils in water-jacketed tanks, each tank containing from 300 to 1300 pounds of soil. Water was applied to the soils, and the soils were cultivated in such manner as to resemble the different methods of treating soils in irrigated fields.

Series of Experiments.

In two experiments with cultivation as soon as possible after the application of water, the losses from cultivated soils were but one-half and one-third, respectively, as great as those from similar soils receiving the same quantities of water, but not cultivated after irrigation. The savings were 5 to 2½ per cent. of the quantities applied in the two experiments.

A second series of experiments included the application of water on the surfaces, not followed by cultivation, and the protection of the wet surfaces by placing upon them mulches of dry soil 4, 8 and 10 inches thick. In this case the losses in fourteen days following irrigation were: From unprotected soil, 23 per cent. of the water applied; from soil protected by a 4-inch mulch, 6 per cent.; from soil protected by an 8-inch mulch, 2½ per cent.; and from soil protected by a 10-inch mulch, 1½ per cent. of the water applied. After these fourteen days the losses from all were substantially uniform.

Another experiment included applying water to the soil at the surface and in furrows 3, 6, 9, and 12 inches deep, all soils being cultivated on the third day after irrigation began. The experiment covered ten days, and at the end of that time the losses were: From the surface-irrigated soil, 24 per cent. of the water applied; from soil irrigated in furrows 3 inches deep, 21 per cent.; in 6-inch furrows, 17 per cent; in 9-inch furrows, 15 per cent.; and in 12-inch furrows, 12 per cent., the loss in the last case being half that in the first.

Value of Experiments.

These experiments related especially to the irrigation of orchards, where it is possible to apply the water at considerable depths and to cultivate the soil to depths of 10 or 12 inches without injury to the trees. Naturally these methods cannot be used in the irrigation of grain and hay, where the water must be applied at or near the surface, nor on crops whose root systems are near the surface, so that deep cultivation cannot be practiced.

They show, however, that where water can be applied in deep furrows, and where irrigation can be followed by deep and thorough cultivation, half the water ordinarily lost by evaporation can be saved, and that this equals 10 to 20 per cent. of the water applied, making possible an extension of, say, 15 per cent. in the area irrigated with a given supply of water. In other words, if land has been receiving a depth of 2 feet of water under the old system, it need receive only 20 inches under the new system, or a stream which has irrigated 100 acres can be made to serve 115 acres.

The report gives a large amount of additional information on evaporation from soils and water surfaces under different conditions.

The bulletin may be obtained of the Superintendent of Documents, Government Printing Office, at 10 cents a copy.

COMPUTING WATER.

The following data will be helpful in computations: One miner's inch, described elsewhere equals 0.1496 gallon per second; 8.976 gallons per minute; 538.56 gallons per hour; 12,925.44 gallons per day; 0.02 cubic foot per second; 1.2 cubic feet per minute; 72 cubic feet per hour. One acre-inch of water (that is, 1 inch in depth over an acre of surface) equals 27,152 gallons, or 3,630 cubic feet, and 1 miner's inch will supply this quantity in about 50.4 hours. Thus a simple calculation shows that a little stream of 5 miners' inches will supply enough water to cover an acre 2.3 inches deep in about 23 hours—a fair amount for one irrigation of soil of average character if it has not been allowed to become too dry before the application; in fact, this is an average amount actually used for an irrigation of shallow-rooted plants like most field and garden crops.

SOURCES OF WATER.

The sources of water supply and methods of use most frequently available for a single farm include the following: Diversion of perennial streams; development in dry stream beds; development of springs; catchment from outcroppings of water-bearing strata; tunneling to intercept such strata when deeply covered; flowing wells; pumping from wells, lakes, or streams, and storage of storm water from surface flow or from drainage systems.

IRRIGATION POINTERS.

Trees are not injured when intelligence enters into the use of water.

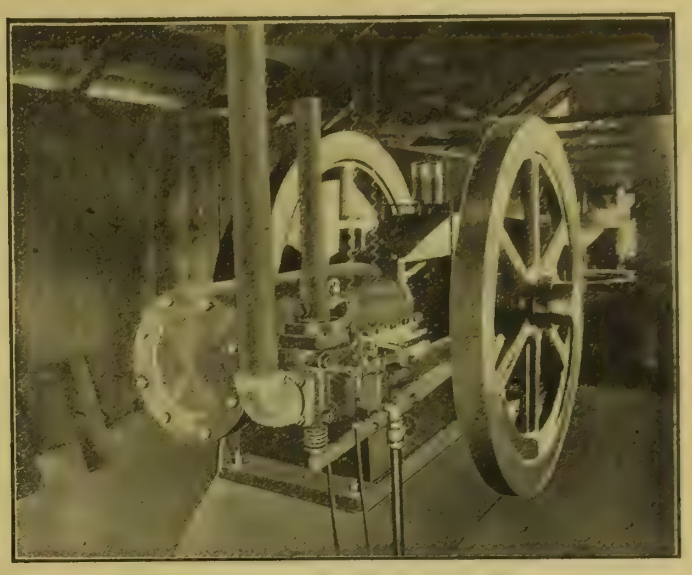
Some kinds of fruit are especially injured by over-irrigation.

Careless irrigation often injures trees and vines.

Demonstrated Economy and Efficiency

ESSENTIALLY AS GOOD as the day it left the factory, this engine is a constant advertisement of the high-grade material and first-class workmanship that enter into the manufacture of every **"Western"** Engine.

Water pumped by F. Lauzier's 60-H.P. "Western"



The First 60-H.P. "Western" Engine

El Monte, Cal., September 24, 1906.

Western Gas Engine Company,
Los Angeles, California.

Gentlemen:

Four years ago I bought a ranch at El Monte, and finding it necessary to install a pumping plant for irrigation purposes, I made a thorough investigation of the different engines and pumps then on the market. As a result of this investigation I decided that the "Western" was by far the ***best engine on the market*** and placed an order with you for a 60-H.P. engine and a No. 8 vertical centrifugal pump. In the three years that I have used it, the engine has demonstrated by its economy, ease of operation and lack of repairs, that my judgment was correct. The engine shows absolutely no sign of wear, and seems to be doing better work today than ever.

We are pumping 200 inches of water against a head of 60 feet on a fuel consumption of 6 gallons of No. 2 Distillate per hour.

I am well pleased with the engine and with the way you have treated me, and can cheerfully recommend you to any one wishing fair treatment and reliable goods. Yours respectfully, F. LAUZIER.

This ranch has recently been sold at a high figure, one of the principal inducements to the purchaser being the fine pumping plant.

90-H.P. "Western" of Western Water and Power Co.

Glendora, Cal., September 4, 1906.

Western Gas Engine Company,
Los Angeles, California.

Gentlemen:

Referring to the 90-H.P. "Western" Gas Engine purchased from you last spring, would say that we commenced operating this engine on July 6th last, since which date it has been going practically continuously day and night.

The engine has been running a Byron Jackson No. 6 Centrifugal Pump, lifting 75 miners' inches of water 200 feet, and has not been operating to near its full capacity; that is to say, we still have a good reserve of power in the engine.

The engine runs very smoothly, requires little attention, and we cheerfully recommend it to parties in need of power.

Yours very truly, WESTERN WATER & POWER CO.
By C. S. Whitcomb, Mgr.

The Wild Flowers of California

Astragalus Brauntonii, a Native Bush Pea

IT IS probable that California never had a better season than the present for the collection of our native plants and their seeds. Abundant rains, coming at opportune times, have accomplished wonders with our wild flowers, especially among herbaceous plants.

Just now, and for two or three weeks to come, one may be able to collect seeds of many plants, like our yellow violet (Viola pedunculata) and the shooting star or wild cyclamen (Dodecatheon media). Both of those mentioned have conspicuous seed pods and the plant is easily recognized. Why not have several of our more showy native flowers close at hand and note the improvement, in size and number of flowers, which comes with cultivation.

As an instance of what can be accomplished, our giant sunflowers of the garden are the same as the "pesky" wild ones which infests our fields and roadsides. Cultivation and selection made the change. Our gorgeous chrysanthemums all came from a little single yellow flower about the size of a nickel. Many of our native flowers are capable of great improvement under but little better conditions than they have on their native heath. Gather seeds of a few this year and give them a trial in the garden.

Coulson's Special Dry Chick Food

Feed to Your Chicks

And See Them Grow

Advantages of Coulson's Ready Mixed Chick Feed

The proper feeding of poultry is without a doubt the most essential factor in the raising of any kind of poultry for profit. Considerable advancement in the feeding of poultry has been made in the past few years, especially in the feeding of little chicks.

Chicks should be given a feed that makes healthy, well developed bodies. COULSON'S SPECIAL DRY CHICK FEED contains the ingredients that are best adapted to give nourishment to the growing chicks: Sweet tender seeds, cracked grains, blown free from dust, cut oat meal, tiny pieces of cooked and dried meat, fine particles of fresh cut bone, charcoal, burnt bone, and other things.

It is clean, sweet feed that is easily digested, and chicks show increase in weight, strength and beauty when fed it exclusively. Little chicks need no other food for the first six weeks. You can feed your chicks entirely on COULSON'S SPECIAL DRY CHICK FEED the first six weeks, at a cost of about 4 cents apiece.

Ask your feed dealer about Coulson's special and be sure that he does not sell you something else.

If your dealer does not keep it, write us, and we will tell you where and how to get it.

To be able to raise the chicks that you hatch and have early broilers to SELL AT A HIGH PRICE; to raise NICE LARGE HEALTHY CHICKS; to have chicks that will stand on the floor and crow when six weeks old; to raise chicks that you will be proud of, feed

SPECIAL OFFER.

Where Coulson's Special Dry Chick Food cannot be obtained from local dealers, we will ship, freight prepaid to any railroad station in California, 100-lb. sack for $4.00 or 200 lbs. for $7.50, cash with the order.

Pullets Lay Early

"I have fed your Special Food and Growing Chick Food to all my stock with one exception. I tried one lot of 350, and fed them my way or raising chicks back East. Results just fair. The other were fed up to three months on your Special Chick Feed, and the results were a surprise to me. The birds were large and the cockerels out of one lot I sold to the California Market and got a big price, with the request to send on to them at any time I had more cockerels of the same quality." Respectfully, A. P. WARD, Calistoga.

Coulson Poultry & Stock Food Co., Petaluma, Cal. Milwaukee, Ore.

Gentlemen:—

While in the poultry business I have tried several brands of Chick Foods and find COULSON'S SPECIAL far superior to any other brand.

Yours truly,

(Signed.) Floyd W. Scott.

Oidium or Powdery Mildew of the Vine

Extracts from Bulletin No. 186, Issued the Present Year by the California Experiment Station

By FREDFRIC T. BIOLETTI, University of California

CALIFORNIA is peculiarly fortunate in its freedom from most of the serious fungous vine diseases which add so much to the expense and uncertainty of grape growing in most countries.

Peronospora, Black Rot, and Anthracnose are here quite unknown. Of the four most serious fungous diseases which attack the above-ground portions of the vine, these three are the most to be feared, as they are not only capable, if neglected, of destroying the whole crop of a vineyard, but require the utmost vigilance and much troublesome treatment with winter washes and summer sprays to hold them in check.

Their absence makes quite unnecessary the swabbing of the dormant vines with sulphate of iron and the spraying of the growing vines with Bordeaux mixture which are adopted here by some vineyardists who have learned the practice in Europe or the Eastern States where it is necessary.

On the other hand, the remaining serious fungous disease—Oidium—exists in all parts of California. From one point of view, this is the most serious disease of the four, as, if uncontrolled, it is capable of spreading more universally through the vineyards and of absolutely destroying the crops in nearly all. From another point of view, it is the least to be feared, as it is possible to control it completely, at least in most parts of California, by much simpler and less expensive methods than are needed for the others mentioned.

Discovery of the Utility of Sulphur.

After 1854, the grape growers of France commenced to learn how to control the disease. The use of sulphur for this purpose, discovered and perfected between 1850 and 1853, soon became general, and by 1859 the crop of grapes had reached its normal volume in France.

The rapidity with which sulphur enabled the French grape growers to re-establish their vineyards is in contrast with the slower process of controlling the phylloxera. In three or four years after the use of sulphur became general in the Herault the crops had reached their normal volume. It has taken twenty years to re-establish the same vineyards on phylloxera resistant stocks.

Damage done by the Disease in California.

In California the Oidium has never produced such wide-spread and serious injury as that indicated above. This arises principally from the dryness and heat of the atmosphere during summer in most of our grape-growing regions. The dryness of our climate is undoubtedly the cause of our immunity to Peronospora, Anthracnose and Black Rot, and while Oidium requires less moisture than these diseases for its development, it spreads more rapidly and is more difficult to control in a moist atmosphere than in a dry one.

At the same time, the Oidium does far more harm, even in California, than is usually suspected, and in certain regions and certain seasons may totally destroy the crop and diminish the crops of following years by injuring the vine.

There has been a recrudescence of the intensity of this disease both in Europe and California during the last few years. This is due, in all probability, not to any change in the fungus or of the seasons, as has been suggested, but to the neglect of regular sulphuring by the grape growers, who have become careless after years of comparative immunity due to more or less general treatment for the disease.

While most grape growers in California sulphur their vines in some way, many of them do not succeed in completely controlling the disease and are often doubtful of the utility of the treatment. Where good sulphur does not give immunity it is because it has not been applied in the right way or at the right time. Many growers who do succeed in keeping their vines free from Oidium do so at the expense of far more sulphur and labor than are necessary.

Description of the Disease.

This disease, usually called Mildew in California, is caused by a fungus belonging to the same group as the fungi which cause the mildews of roses, hops and apples and is generally referred to as Oidium in Europe. The disease known as Mildew or Peronospora in Europe and the East is totally different and caused by a fungus of very different character. In order to distinguish the two, the Oidium is sometimes called Powdery Mildew and the Peronospora, Downy Mildew. As only one exists in California, the use of the word Mildew should lead to no confusion, though perhaps it is best to adopt Oidium as the name of this disease.

Symptoms and Effect on the Vine.

The Oidium attacks all herbaceous parts of the vine,—leaves, canes, flowers and fruit. In the spring, the young leaves which are attacked show at first whitish patches about one-quarter of an inch in diameter on the upper or lower surface.

As the disease progresses these patches run together until a large part of the surface of the leaf may be covered with a grayish white mildew. The leaf ceases to grow and curls up towards its upper surface.

As the shoots lengthen, the canes may be attacked in the same way. The patches of mildew appear usually near the bases of the canes and are difficult to see until they acquire the gray tint. In severe cases, the fungus may completely cover the whole surface of the cane, but it is usually confined to patches. If these patches are rubbed the fungus comes off completely. The places where it has been, however, will turn dark later owing to injuries to the superficial cells of the bark.

These marks, at first brown, later black, are usually branching or fern-like in form, showing the points of attack of the fungus. If the canes are atacked when young, they fail to mature properly and often turn black over their whole surface. It is this form of Odium which has sometimes been mistaken for Anthracnose in California.

Later, the blossoms and fruit may be attacked. When the blossoms are attacked they fail to set, and if the berries are attacked when very small, they will fail to develop and will drop off. If the fruit reaches nearly full size before being affected, it continues to develop, but irregularly. The parts of the epidermis injured by the fungus become hardened and cease to grow. This results in irregularity in the form of the berry and in severe cases in cracking.

If this cracking occurs early, the grapes dry up completely before ripening. If later, they may develop sugar and can be used for wine making, but the crop is diminished in volume. In moist seasons the berries which are cracked usually become the prey of blue mould and are completely destroyed.

After the grapes have lost the green color due to the presence of chlorophyll in the skin and have commenced to ripen they are not attacked by Oidium. The markings and blotches which are often seen on ripe grapes are due to injuries to the skin caused by the presence of the fungus on the grapes before they ripened. If the attack has not been early or serious enough to prevent the grapes reaching normal size they may still make good wine. The markings, however, are very objectionable on table and raisin grapes and decrease their value.

Tokay and Muscat grapes often show the dark, fern-like markings characteristic of the disease similar to those shown on the canes. When abundant, these markings, which are accompanied by a thickening of skin, injure the appearance of the raisins. Where the skin of the Muscat grape has been attacked by Oidium it will remain smooth after drying and not show the fine wrinkling characteristic of the finest raisins.

A vine of which the leaves are badly attacked has a peculiar color and wilted appearance. This appearance is only shown when the conditions of temperature and moisture are favorable to the growth of the fungus on the exterior leaves. This can occur only at the beginning of the season in the warmer and drier parts of the state. When the air is hot and dry the fungus cannot grow on the outer leaves. The proper favorable conditions, however, may still exist in the interior of the vine. For this reason vines may look perfectly healthy from a little distance, while the fruit and the bases of the canes may be covered with Oidium. A vine which is badly attacked has a moldly smell readily perceptible to many people.

Description of the Fungus.

The botanical name of the fungus is Uncinula spiralis (Berkeley and Cooke), and it belongs to the family or group of Erysiphae. All the members of this family are parasites which live upon the outer surfaces of leaves and other green organs of plants. The white "mildew" which they form on these surfaces consists of the branching threads or mycelium, which constitute the vegetative body of the fungus.

This mycelium grows only on the surface, unlike the mycelia of Peronospora and other parasitic fungi which enter the tissues of the host plant. It obtains its nourishment from the epidermal cells of the plant attacked, by means of suckers—haustoria—which penetrate these outer cells. The outer cells thus attacked become dark colored. The fact that the Oidium does not penetrate the tissues of the vine much facilitates its control and renders its destruction possible at any stage without injury to the host plant from the remedies applied.

Deciduous Fruit Culture

By J. W. MILLS

CANNING PEACHES.

IT has been a problem in the past, to know just what to plant in the line of canning peaches.

The canner will advocate one kind one season, and if he happens to get some fruit that strikes his fancy as a little better than the average, he advises prospective planters to get that variety even though there are none on the market in quantities for even a small commercial planting.

The nursery men knowing how such things go, refuse to be drawn into the quandary further than growing a few of varieties other than the standard sorts. If they did otherwise, we would not have had any nurserymen in a few years. They would have become bankrupt.

The Best Kinds.

For a number of years, Lemon Cling was demanded by the canners as a leader for fancy fruit. It brought the highest price of any yellow cling for a number of years.

Its one great fault was its small size. The grower has difficulty in coaxing it up to canning sizes and there are always a large percentage of culls due to small size. It is, or was till the Phillip's Cling came out, the best looking canner peach to be had.

The bright color and clear juice gives it an attractive appearance that takes the eye of the jobber. Growers generally consider any good-sized yellow Cling as good as any and especially if he raises it himself.

The fact of the matter is, there are but two or three yellow Clingstone peaches that show up well after they get on the Eastern market. Little particles of fiber separate from the body of the fruit and by the time the fruit gets across the continent and in the hands of the dealer at the other end, the jar of the cars and trucks produce a cloudy juice.

Growers do not appreciate these facts and are prone to blame the canners for being changeable and unreasonable in their requests regarding varieties. When he follows his fruit across the continent and sees these things and his brand is lowered on the standard even slightly, it counts against both the canner and grower.

A Good Test.

A Southern California canner made tests with several varieties of yellow Clings some years ago, and when these peaches were put in glass exhibitions jars, all but one variety had to be placed in water in order to get a clear, bright appearance. One variety, yellow Tuscan had a bright, clear syrup. Seller's Cling came next in quality.

Tuscan Cling was one time an extra fine canning peach, but is now being left in the race with formally top-notch peaches. This variety was given about ten years ago, but since that time it has brought good money and in fact has paid better than any peach in Southern California.

It is very prolific and is inclined to overbear where other varieties are practically failures For this reason it will be the leading canning peach for the southern end of the state till some untried variety proves to be its superior.

Phillip's Cling has now been on the market for a number of years and has proven that it is the best yet for Northern California. Aside from having good canning qualities that the best of other varieties have, it has a small pit which gives even the smaller sizes a larger appearance than the same sizes of other varieties. There is also more net weight in a given amount of Phillip's Cling, there being a comparatively thick flesh.

The devouring appetite of the law-protected quail is causing great uneasiness among the alfalfa growers in Cottonwood Creek, in Tehama county. It is said these birds are eating up whole patches of alfalfa.

PLACER COUNTY ORCHARDS.

I believe that one of our very popular and almost universal ways of extracting fruit from our hillsides is radically wrong and calculated to soon render it almost impossible to get any more good fruit, except from new land. If this is true it is certainly a subject worthy of discussion and of careful thought on the part of land owners and of any others interested in a wise public policy.

I refer to the practice of thorough and industrious plowing and cultivation of these hillsides, in which we have always taken such a virtuous delight and in which nearly all the authorities on such matters have constantly encouraged us. (The writer is somewhat wrong on this point. Not all good authority in California today advocates clean winter culture. Ed.)

When we first clear a Placer county hillside, in the fruit district, the soil contains a liberal supply of all of the chemical elements necessary to produce large crops of the finest of fruit.

Washing out the Soil.

Heretofore the ideal of the "good husbandman" has been to remove every vestige of grass from his orchard and when he has done that there is nothing to hold the soil in place and its lighter element, the precious humus, soon finds its way into one of the muddy torrents that flow from the lower side of a "well" cultivated orchard on a rainy day.

After watching this process for years I am convinced that the deterioration of the soil of our hillsides is due to this cause almost altogether and not to the chemical exhaustion we are told of by the fertilizer man.

Positive Proof Present.

In proof of this conclusion I may say that a hillside that has been cultivated for a number of years will show almost the same deterioration whether it has produced heavy crops or no crops at all; that the producing power has diminished just exactly as the visible supply of humus has disappeared, and that this has disappeared just as the color of the soil has changed from a rich dark brown to the color of the underlying rock, generally a glaring red.

During this same time the soil has lost its mellow, loamy character and has taken on many of the characteristice of Portland cement, consisting simply of particles of rock, big and little, with very little of anything else between. A little careful study of any of the older orchards (well cultivated ones) will bear me out.

The Writer's Conclusions.

In endeavoring to remedy this trouble I at first aimed to plow under as much green grass as possible, but it didn't do much good and, when I came to think of it, I found that Nature don't use green grass in her work. She allows it to grow to maturity, to harden, dry and die before she begins to make soil of it.

And so I evolved my scheme of plowing alternate "middles" on alternate years, "crossways" of the natural flow of rain and irrigating water, and of allowing Nature a chance to work in her own way to repair the damage which I had wrought. Now, when a particle of humus washes off a plowed "middle" it is caught by the grass on the unplowed "middle" below and the water leaves the bottom of the orchard almost as clear as it leaves one of Nature's grassy hillsides.

When I started this plan five years ago I could scarcely average two inches of grass, now I can get nearer two feet. The fact of lying unplowed for a year and then the plowing under of a good crop of decaying matured grass every second spring, has a most noticeable effect on the soil. It is fast taking on the appearance and characteristics of virgin soil and I have lately found experts who say that, when soil is in this condition, Nature has little trouble in providing the chemicals.

At first this plan required a little more water but now not so much. The

Full Protection

to your stock, grain and implements requires the right kind of a roof.

REX FLINTKOTE ROOFING

for all the farm

REX Flintkote ROOFING is not only absolutely water-proof, but wind, cold and heat-proof, and fire-resisting

plowing of alternate "middles" acts as a protection from fire and altogether the plan might be worth a trial by some of the wise ones. I know of several places where something will have to be tried soon.—G. Geraldson.

FUMIGATION FOR THE DESTRUCTION OF INSECT PESTS.

The fact has been well established that for the thorough extermination of the insect pests that infest our cultivated trees and plants there is nothing that equals the fumigation with hydrocyanic acid gas.

This is particularly true of those insects that infest our greenhouses. Here spraying with the ordinary fungicide and insecticide mixtures is not available, because of the injury to the appearance of ornamental plants and to the paint on these structures. Fumigation then becomes the only available and efficient remedy.

This is also true in the case of the nurserymen who wish to avoid the risk of sending out infested stock, even where they are reasonably sure that their stock is not infested. In fact in many states the law now requires that all nursery stock shall be fumigated before shipment. While the great expense of tents, etc., may operate in many instances against efforts at fumigation in the orchard, there is no doubt that even there the complete eradication of the pests would make the process cheap, as compared with the partial destruction of the trees by spraying, since one fumigation would certainly last for the season at least.

But in the case of the florists and the nurseryman, fumigation is really the only effective remedy. Hence it becomes necessary for them to study the methods and materials used in order to learn the most economical and practical way of doing the work. The usual method has been to develop hydrocyanic gas by dropping cyanide of potash into sulphuric acid in a closed house. But lately there has been an effort made to show that cyanide of potash may be more economically replaced by the cyanide of sodium. When a nurseryman is told that 100 kilograms of cyanide of sodium will produce as much hydrocyanic gas as 132 kilograms of cyanide of potash, he is apt to at once jump at the conclusion that the sodium cyanide can be used as a cheap substitute for the potassium salt. But a test will prove that the actual amount of the gas liberated is less than tht amount of gas released by the potassium cyanide, because when the sodium salt is treated with sulphuric acid, a residue forms consisting partly of solidified sulphate of soda and partly of undecomposed cyanide of soda.

On the other hand, the residue left from the use of potassium cyanide is not a solidified mass of useless material, but crumbles to a powder. This powder is not a valueless article to the cultivator, like the sodium sulphate, but is the potassium sulphate that commands a high price as a fertilizer. This fact that the residium from the potash salt is a valuable fertilizer will of itself do away with all claims made for the superior economy of the sodium cyanide, even if the claims for a larger production of gas had to be granted, for the residue resulting from the use of the sodium cyanide is a perfectly worthless article to the cultivator, while the residue from the potash salt is sulphate of potassium in a readily available form that would command on the market over $2.50 per 100 pounds as a fertilizer. From this we see how important it is for the grower to study all the actual facts in connection with the process.—W. F. Massey,, Editor of "Practical Farmer."

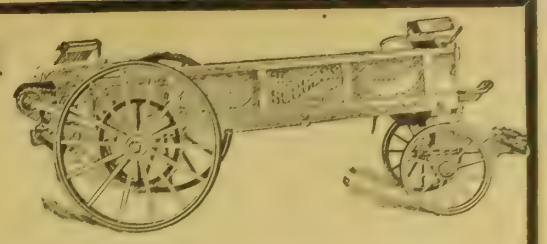
If the weather changes to clear and warmer the chances are still good for a peach crop about Newcastle. Elbertas are curling badly and may be defoliated. However, if the trees are vigorous they will push out new foliage and mature a good crop, other conditions being favorable.

Trees are injured by too much irrigation and not sufficient cultivation.

GOVERNMENT AID FOR ORCHARDS.

Among other matters provided for in the Agricultural Appropriation Bill passed by Congress is a special appropriation for the purpose of investigating the thrips in California. The thrips has become a serious pest especially in the prune orchards of the Santa Clara valley in the past few years, and it is to be hoped that the federal investigation will develop some practical method of checking it. The thrips is an exceedingly small insect, barely visible to the naked eye, and its favorite haunt is in the opening blossoms of flowers, especially in those of the plum family, where they congregate in enormous quantities and devour the essential organs of the blossoms, thereby destroying their fertility and at the same time destroying all hopes of a crop. At the present time we know of no effective parasitic enemy of this pest and of no effective artificial remedy, and, as it is a very serious menace to our fruit growers, we have cause to be pleased that the government has taken up the work and to wish it every success therein.

Don't buy a Manure Spreader —without seeing it.



And after you have seen it, inquire into its record. Ask some practical man who has used one what he thinks of it. Ask him—

How long he has used it?—What it has cost him for repairs?—Whether it is easily operated?

The Success Manure Spreader

is the result of 28 years' experience in making spreaders, during which time every new device has been tested and those of merit adopted.

There's nothing startling about the Success,—just plain proven worth all the way through.

These points of construction indicate its genuineness

Largest of axles, we've tried smaller ones

Tough second-growth white ash frame—no other wood is as good

Beater braced to axle with steel shaft, throwing strain on axle instead of end of body.

Apron on three series of stationary rollers. No chance to bind

Harpoon teeth on beater. (New feature.) Keep beater ends clean.

Apron returns in driving 65 feet after load is off.

Spreading Mechanism absolutely locks in or out of gear. No racing of Apron in going up or down hill

Our special book on Spreaders will help you. It presents plainly and truthfully the facts in reference to Success Spreaders. Write for it before you buy but, most important of all, ask some one who has used a Success.

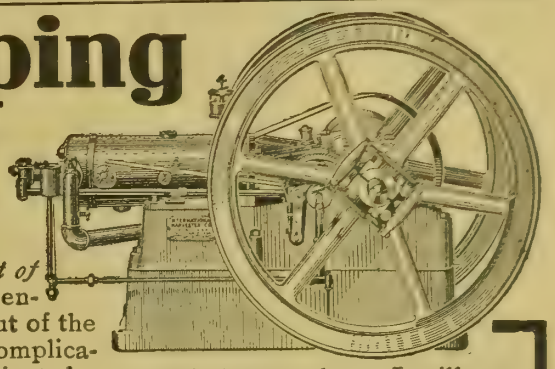
Irrigation Pumping

is done easily and economically with an

I. H. C. Gasoline Engine



WHETHER you are pumping from deep wells, shallow wells, reservoirs, canals, or running streams, an I. H. C. gasoline engine is the one best power.

It is the best for a number of reasons.

In the first place, it is *easily operated.* You don't need an engineer to look after it—in fact it requires practically no attention whatever—it will run for hours at a time, safely and regularly, and when it does needattention, your small boy or girl can look after it as well as you can.

Next it will *not get out of order.* I. H. C. gasoline engines are made throughout of the best materials, and all complicated parts have been eliminated.

And again, it is economical.

Ordinary stove gasoline is the fuel it uses, and it gets all the power out of it and wastes no fuel. And gasoline is something you can always have ready. Buy it by the barrel, and it is easy to keep a supply on hand.

And there are many other features which we can't go on to explain here—durability, safety, convenience, etc. Investigate them before you buy. It will pay you to know all about them.

I. H. C. gasoline engines are made in various styles,—Vertical and Horizontal, Stationary and Portable, and in sizes ranging from 2 to 20-horse power. When not in use for pumping they furnish excellent power for sawing wood, cleaning grain, grinding feed, shredding fodder, separating cream, etc.

Live Stock and Dairy

By Mrs. Minna E. Sherman, Fresno, Cal.

MAMMITIS.

THE dairyman calls this trouble with a cow's udder garget. The spring time brings many cases; usually, however, they are of a wild type. When the udder is found to be inflamed it should be bathed with hot water or fomented.

A simple equipment for this purpose is a small coal oil stove and teakettle to hold water. The oil stove will keep a kettle of hot water at the boiling point, then a pail of hot water is carried to the cow's side with pieces of woolen blanketing about a yard square, one piece is wrung out of the boiling water and held closely over the udder, when it becomes cool the other piece is used hot, never leaving the udder uncovered for more than a minute at a time.

Keep the water hot in the pail by adding to it from the kettle from time to time. After twenty minutes of fomenting, gently milk out all the milk that will flow, then rub the udder with olive oil, or hot lard, or use the following lotion after the hot fomentation: Acetate of lead, half an ounce; sulphate of zinc, half an ounce; soft water, one quart, shake before using and rub the udder with the bare hands until dry.

Protecting the Udder.

Cover the udder from the air by using a doubled flour sack. This can be loosely run around the edges with a piece of string to make a bag, then draw it over the udder.

Use a piece of soft rope to hang the sack from the cow's back. A piece of folded sacking tied under the rope and over the center of the cow's back will keep the rope from chaffing the skin over the backbone. One, two or three fomentations a day will soon bring the udder into healthy conditions.

Internal Medicine.

To help reduce the inflammation by cooling the blood, give one to one and half pounds of Epsom salts with a couple of tablespoonsful of ground ginger, dissolve the salts in half a gallon of warm water and drench the cow.

The usual cause of garget is cold, for the udder is not full of warm blood as it is far from the heart and lungs—it is really an extremity. When the cow lays down on damp ground and the udder is engorged with milk-making material the circulation is poor and a local chill is readily caught. Garget may be produced by blows from cruel milkers, or it may come from being horned or butted by other cows; sometimes it comes from mere over distention of the udder from too much milk.

Frequent Milking.

The heavy milking cow should be relieved of her milk three times a day, during the flush of freshness when on green pastures.

A cow that gives over thirty pounds a day when fresh milked three times a day will give an increased flow of milk. It pays to make it a business of having every cow milked three times a day when fresh; even heifers are developed rapidly and the good habit of large yielding is established early in their lives. I was told that the cows that are now making records of over a pound of butter fat a day, eight or ten months from calving, were all milked for four or five months three times a day even as heifers. It is only with the milk-bred and well-fed cow that this is worth while to put into practice.

Acute Garget.

When the udder is greatly inflammed the milk may be curdled and heavy curds formed; if, when the cow has had the udder thoroughly fomented, the milk comes in shreds and strings and finally stops flowing altogether, the case is a bad one and must be promptly believed if the udder is to be saved.

If the case had been promptly handled with hot fomentation and then kept milked out this further complication would not have occurred. Sometimes the milkers will conceal the condition of a cow and the case becomes bad before it is discovered. When the teats are choked with curd then the milking tubes must be resorted to—to help clear them out.

Milking Tubes.

Every herdsman should have four silver milking tubes, as they may all be at times needed. It is necessary that the tubes be bacterially clean or else the case will be aggravated instead of relieved.

Tie a bit of thread to each tube and put them into a kettle and boil them well. Have a narrow wide mouth vial full of carbolized vaseline, put the hot tubes into it and keep them there until used. A rubber bag with a long rubber hose is used to flush the udder with. Run hot water with a corrosive sublimate tablet dissolved in it through the tubing and bag to sterilize it. Boil a kettle full of fresh water, putting a teaspoonful of baking soda to each quart of water. When boiled stop the nose of the kettle with a bit of cotton and take the kettle, the milking tubes and the fomenting pail and bits of blankets and proceed to the barn.

Treatment.

At the patient's side milk out first gently all the fluids that will pass the teats. Then insert carefully a milk tube into each affected teat, avoid touching the part of the milking tube that is inserted with the fingers, holding it by the lower end.

Fill the rubber bag with the water from the teakettle that has the baking soda in it. The temperature of the water should be about one hundred degrees. Fill the bag, attach the hose to the end of the milking tube, and let the water flow gently into the udder. When all the water has passed into the udder that it will take, draw out milking tube, lay to one side, and if another teat requires treatment take a fresh tube from the carbolized vaseline and repeat the process. The milking tubes must be sterilized before using again.

Fomentations.

The udder is then well fomented as before described, and then is milked out again, this time drawing out the soda water which it will be found has acted on the curds in making them soluable.

If the calf is not too old it should be allowed to nurse for a few days. If the cow is a heavy milker, draw some of the milk twice a day and let the calf stay by the cow. The maternal instinct is strong and the cow will allow the calf to have its rightful portion even if it is a little painful. If the milk is partly removed by hand milking the calf will be hungry enough to be persistent in taking the milk as fast as formed.

Abscessing.

The quarter of the udder affected may become greatly swollen and finally form an abscess, the pus formed will burrow its way downward and break at the lowest point usually at the base of a teat, it leaves a raw opening, sometimes the teat drops off entirely.

A Case at Home.

On the ranch a heavy milking cow freshened during a severe illness of a member of the family; neither the wise man or the madame were able to see after this cow for several days. The udder was greatly inflamed, the cow was in a high fever, no remedies availed, and in twenty-four hours gangrene of the udder had set in; the usefulness of the udder was gone, and the treatment was to save the cow's life.

Creolin was sprayed onto the diseased portion freely, and in forty-eight hours the diseased portion of the udder dropped off, leaving only one quarter. The portion left was healthy, and the raw surface was kept dusted with iodoform, when it healed rapidly and the cow was saved. This cow from one teat and a quarter of an udder is now giving 26 pounds of milk daily. This is nature's way, she will develop that remaining portion of the udder to a surprising extent if

Warranted to give satisfaction.

When writing advertisers mention Cultivator

helped along with careful milking. It will be of interest to see how much more this cow will develop, as she is now giving half a normal flow from a quarter of an udder.

Usually Fatal.

The experiment is one that is not often tried for usually a heavy milking cow with an udder in the condition that this one was in dies. This cow for twenty-four hours was in a critical condition.

The wise man took his rifle to the corral to end her sufferings at once but she turned and looked at him with her mellow eyes, he put away the rifle saying: "She shall have her chance, for her eyes look too much like a woman in pain. I cannot shoot her." The next morning the udder dropped away and left a clean, healthy surface, the fever passed, and the cow was convalescent.

THE MILKING MACHINE.

The following summary of results of bacterial investigation in connection with the use of the milking machine is taken from a bulletin of the United States Agricultural Department:

1. Unless sufficient care is used in cleaning the machines, decaying milk and bacteria accumulate in the rubber tubes and contaminate the milk as it passes through them.

2. The few dairymen now using these machines are not exercising sufficient care in washing and sterilizing the machines to keep them in sanitary condition; their milk is therefore of poorer quality from the sanitary standpoint than that drawn by hand under the same stable conditions.

3. Good sanitary conditions in a stable may be completely counteracted by the insanitary conditions of the milking machine.

4. When kept in fairly clean condition the machine-drawn milk contains decidedly smaller numbers of bacteria than the corresponding hand-drawn milk.

5. When the machines are not well cleaned both the number and percentage of acid-producing bacteria are higher than in the hand-drawn milk, but when they are fairly well cleaned both the total number and the percentage of these bacteria are decidedly lower than in the corresponding hand-drawn milk.

6. Both the total number and the percentage of liquefying bacteria found in the milk were in most cases greatly reduced by the use of the machines. This fact is of special significance in milk designed for direct consumption.

7. When properly cared for, drawing the milk by means of the machine increases its keeping quality.

8. Washing the machines with cold water and then with hot water containing sal soda is not sufficient to keep the rubber tubes clean. Under this treatment the inside of the tubes becomes coated with decaying milk, thus forming ideal conditions for the multiplication of various species of bacteria.

9. Scalding the machines by pumping boiling water through them just before use had little or no effect in reducing germ content of the milk.

10. Boiling in clear water for three-quarters of an hour was not sufficient to keep the rubber tubes in a sterile condition.

11. Subjection to steam without pressure for thirty minutes was not sufficient to sterilize the rubber tubes.

12. Placing the rubber parts in brine for several hours after being washed reduced the germ content of the machine-drawn milk to about one-half that of the milk drawn by hand.

13. Boiling in water containing a small amount of powdered borax had about the same effect in reducing the bacterial content of the milk as did the brine treatment, but the use of borax is dangerous unless extreme care is exercised.

14. The machines may be very effective in the production of sanitary milk if they are properly cleaned and sterilized.

15. The results of these experiments indicate that the machines may be kept in such an insanitary condition that the keeping quality will not be improved, but may be seriously impaired. They also indicate that with properly cleaned and sterilized machines the keeping quality of the milk may be very materially improved.

SEPARATOR CREAM.

The following nine terse advices are synopses from as many articles on the subject published by the "Cream Bulletin" published at Stockton:

1. Keep cows, barns, etc., free from odors. Before milking each cow rub sides and udder with damp cloth. Milk with clean hands and never wet teats. Don't smoke while milking.

Keep separator and house clean and create a draught through it. Separate while milk is warm. Never mix warm and cold cream. Cool cream to 60 degrees. Set cream in tub of cold water. Wrap double barley sacks around can; wet them thoroughly and set in draught. Pour cold water on sacks once or twice a day. Cover can with clean, damp cloth or fine screen. Skim a 35 to 40 per cent. cream. Heavy cream keeps better and leaves more skim milk for the dairyman.

2. Keep separator and cans perfectly clean. Cool cream before putting in delivery can. This can be done by using home-made cooler (a light frame, covered with burlap) and allow water to drip from vessel on top. Place cooler in shade, where air can strike it. Heavy cream is best for keeping in good condition.

3. Cream can is placed in cold water as soon as separated and thoroughly cooled. Cloths wrung out of cold water fastened around can; or place cans in home-made cooler during day. Sew grain sacks around cans and plunge into cold water before cream is poured in.

4. Keep everything clean and sweet. Use two separate vessels to hold cream and set in tub of cold water, changing it every 12 hours, keeping tub where current of air will circulate. Cream should test from 45 to 50 per cent. Do not mix cream until cool.

5. Keep separator and milk vessels clean. As soon as cream is separated place can in cold water. Stir cream gently until cool. Let stand in water over night. In the morning run cream into separate vessel and treat as night before. Allow it to stand 30 to 40 minutes before mixing.

6. Use clean pails, cans and milk strainers and place cloth over strainers. Separate twice a day. Put cream in clean can and give it plenty of air, then set in cool place. Send to creamery every 48 hours.

7. Urges perfect cleanliness in utensils. Place can of cream near an open window, preferably northwest, and get free circulation of air. Cover can with thin, damp cloth. Wrap can in heavy, wet cloth or sack. Keep cream well stirred, twice a day, at least, before new cream is added.

8. Clean and scald separator. Put cream in separate vessels and set in cold water in cool, shady place. Cows' udders should be brushed. Separate twice a day.

9. Keep cows' udders, stanchions, buckets, separators, etc., thoroughly clean. Wash separator after each skimming. Cool cream as soon as possible. Keep cans in cold water. Never mix cream until thoroughly cool.

A THALHEIM PLAN.

In reply to your request in the Cream Bulletin for articles on best method of handling farm separator cream, I will try to describe my plan:

The first requisite to keep cream sweet and in a good condition is cleanliness with everything where cream comes in contact. After separating it, the cream has to be cooled as quick as possible, stirring it several times while cooling. Never add warm cream to cold, then keep it as cold as possible, by placing in a so-called cooler, and always keep the cans well covered while carrying the cream to the creamery or station, to keep off the sun and dirt. If this plan is followed, the cream will reach the creamery in a condition to be manufactured into the highest grade of gilt-edged butter.—Wm. Kroeger Thalheim.

Sorghum is grown for pasture, soiling (green feeding), hay, fodder, silage and seed. Methods of harvesting, curing and storing vary with the use made of the crop.

Driver or Worker

To do his best, a horse needs the whole food value of his ration. To produce flesh and milk this is also true. In a heavy fed animal only about half of the food is usually digested, in an unthrifty animal it is less.

Dr. Hess Stock Food the prescription of Dr. Hess (M. D., D. V. S.) increases the powers of digestion and assimilation and makes every pound of grain yield a larger amount of profit than is possible without it, besides curing the minor stock ailments. When we remember it is not the food consumed but the food digested that produces the profit, we comprehend the necessity for tonics. Professors Quitman, Winslow, Finlay Dun and all the leading medical authorities recommend the bitter tonics in

DR HESS STOCK FOOD ATONIC

for improving digestion, iron for the blood, nitrates for expelling poisonous material from the system and besides it is

Sold on a written Guarantee.

100 lbs. $7.00 25 lb. pail $2.00

Smaller quantities at a slight advance.

Where Dr. Hess Stock Food differs in particular is in the dose—it's small and fed but twice a day, which proves it has the most digestive strength to the pound. Our Government recognizes Dr. Hess Stock Food as a medicinal tonic and this paper is back of the guarantee. If your dealer cannot supply you, we will.

The Ornamental Garden

By ERNEST BRAUNTON

EUCALYPTS IN THE NORTH.

"THE GROWING of Eucalypts is beginning to attract considerable attention in many sections of the state, and while possibly rather extravagant claims are made in some cases, there is no doubt but if proper varieties are planted good returns can be secured. The well-known Blue Gum, which is so common in this section, is possibly the least valuable of all, and there is no reason why the land now occupied by them should not be utilized for more valuable varieties.

"L. J. Harbinson interested himself in this matter three years ago and secured from the state university a number of young trees for the purpose of testing their adaptability to this section. Each year since then he has obtained more, until now he has about 3000 trees of different varieties. As a result of his observations up to the present time, he thinks the Red Gum (E. Rostrata) the most promising. These trees are rapid growers and are not in the least affected by the heat of summer or the cold of winter. The Sugar Gum (E. Corynocalyx), on the other hand, will stand neither. The Forest Red Gum (E. Tereticornis) has not yet been tried, but Mr. Harbison believes it will do well, while the Red Mahogany (E. Resinifera) also seems to be adapted to this climate. The Blue Gum is not considered fit for anything except stove wood, and on account of its grain, is exceedingly difficult to work up for that purpose."

"Two fine specimens of the Red Ironbark (E. Sideroxylon) can be seen on G. O. Coburn's place near town. These trees are about thirty years old and measure about twenty inches in diameter."

The above article was taken from a northern paper, but we neglected to observe the name. It would not pay to root out blue gums where now growing and plant to other kinds, for such plantations will prove sufficiently remunerative to satisfy the owner.

There is no doubt, however, but better kinds should be planted in the future, both for fuel and timber purposes. The Blue Gum outstrips all others in rapidity of growth, but even for fuel is not so lasting as any of the other species most common.

On the contrary, it has not proven harder to work up than other species; neither is it true that the Sugar Gum will not stand the summer's heat, for in Arizona it has withstood, successfully, heat such as no part of California ever has. E. rudis seems to bear up under most unusual heat. E. sideroxylon, above mentioned, will not stand nearly so much heat as the Sugar Gum, and we fear there must be some question as to the identity of some species above listed.

Eucalyptus rostrata, the larger of two "Red Gums" and the one usually known by that name in the local trade, is one of the best all-round timber trees to be found. Perhaps no other Eucalypt will grow in such a variety of soils and situations. "It will thrive in soil periodically inundated for a considerable time," yet does well with us in the driest places. "The timber, among that of Eucalypts, is one of the most highly esteemed in all Australia, being heavy, hard, strong and extremely durable, either above or under ground or in water. For these reasons it is highly prized for fenceposts, piles and railway sleepers; for the latter purpose it will last at least a dozen years, but if well selected much longer. Whenever practicable the Victorian Government has discarded the use of any other timber for railways and bridges. It is also extensively employed by ship builders. Also used by wheelwrights and other mechanics. Also best for withstanding attacks of teredo, white ants and other insects." What more could be said for a timber?

Orland shipped three cars of mules last week.

TRANSPLANTING FOREST TREES

The tree planter should endeavor always to transplant his trees with the least exposure of the roots.

The root-hairs, or feeding cells, of the roots of a plant will shrivel up and perish if exposed to the dry atmosphere for even a few minutes.

The roots of conifers are particularly sensitive, so that these require more careful attention in transplanting than do broadleaf trees. Some of the broadleaf species may have their roots dried out and shriveled, yet with proper attention revive and live; but the conifers, once dried, rarely regain their vitality.

The Proper Season.

The best time to transplant young trees is just before growth begins in the spring, when the seedlings are likely to receive the least injury. In general, planting should be done as soon as possible after the frost is out of the ground, the exact period depending upon local climate and soil conditions. In parts of the country where the winter is the only season with an abundant rainfall, the transplanting should be done during the rainy season.

Conifers, with the exception of the deciduous species, such as European larch and tamarack, may be safely planted somewhat later in the season than broadleaf trees.

It is always well to choose a wet or cloudy day for transplanting, but if the work must be done in dry weather the nursery beds or trenches should be thoroughly soaked a few days before removing the trees. By establishing a home nursery close to the planting site the disadvantage of shipment may be avoided, some expense may be saved, and the time for planting may be considerably extended.

The last point is often of importance, because it may be inconvenient to drop other work in order to give a shipment of trees the immediate attention they require. Home-grown stock may be left in the nursery until a favorable opportunity for getting out the trees occurs.

THE AMERICAN CHESTNUT.

The chestnut is distributed throughout the eastern part of the United States at elevations varying from sea level in Massachusetts to 5000 feet in North Carolina.

It ranges from southern Maine southward through New England, but in this region is most abundant in the lower valleys of the Merrimac and Connecticut rivers. Except near the sea, it is common in Rhode Island and Connecticut and as far south as Delaware.

It is found also in the Province of Ontario and in the Eastern States, especially in New Jersey, Pennsylvania, and parts of Maryland. Further south it is found along the Appalachians to Alabama, growing well in all soils above 2000 feet in elevation but less abundantly below. In the Middle West it is confined to Michigan, Indiana and Illinois.

Large areas throughout the East, particularly in New England, New York, Pennsylvania and Maryland, are well adapted to chestnut. Outside of its natural range, however the success of this species is doubtful.

Chestnut can be grown fairly well throughout Missouri and southeastern Iowa, in the eastern counties of Nebraska and Kansas, and in the southern half of Minnesota, but nowhere on prairie soil is it long-lived or of first-rate growth.

In Colorado it grows well under irrigation, and would probably succeed in other parts of the West if well watered. If it is planted too far north the shoots fail to become woody, before they are nipped by the early frosts. The tree will endure the heat and cold of its natural home and will remain thrifty in sunny, dry situations, but is very susceptible to injury from hot winds. Chestnut will thrive on a variety of soils, from almost pure sand to coarse gravels and shales.

With the Citrus Growers

SEEDLING TREES.

WHEN seedling trees are to be used, the selection of seed becomes an important feature. Any and every orange seed should not be used. On the contrary, the greatest care should be exercised in selection.

It is not an uncommon report that seeds of sweet oranges frequently produce sour oranges, and vice versa, but this is probably never true unless the seeds are the result of hybridization. It is well recognized by growers in Florida, California and Italy that when seeds of a sweet orange are planted, trees bearing sweet fruit, of a fairly good character, almost invariably result.

Orange trees, however, are generally grown in close proximity to lemons, limes, sour oranges, pomelos, etc., and it is not to be wondered at if hybridization occasionally occurs. When hybridized with the sour orange, lemon, etc., the resulting seedlings may naturally be expected to produce sour, unmarketable fruit, or fruit with rough and unsightly skin.

While seedlings of the sweet orange almost invariably produce sweet fruit similar to that produced by the parent, there is nevertheless considerable variation wholly aside from that resulting from crossing and hybridizing. This uncertainty as to fruits, especially the finer sorts, reproducing themselves true to seed is what renders budding and grafting desirable in the orange as in other fruit industries.

Where sweet seedlings, or in fact any kind of seedlings, are to be grown, the seeds should be taken from selected seedling trees known to produce good fruit and which are isolated from citrus trees of other varieties or species. Such selection would prevent the probability of obtaining seeds affected by crossing or hybridizing with other varieties, and make it reasonably sure that seedling trees producing good fruit would be obtained.

Pomelos, lemons, limes, citrons, kumquats and the various other species of citrus fruits are almost invariably produced true by the seed, as in the case of the orange, that is, pomelos produce pomelos, lemons produce lemons, etc. Like other fruit trees, however, the different varieties of the fruits named do not reproduce themselves true from the seed. Seeding pomelo, or grape-fruit, trees are quite common in Florida. The varieties, however, have not been so much improved as in the case of the orange, and as yet there is but little difference between the fruit of seedlings and that of the best named varieties.

The principal varieties or subspecies of mandarin oranges cultivated in Florida, known as the China (commonly called Mandarin), Tangerine, King and Satsuma, are not infrequently propagated by the seed, and with but slight variation they commonly reproduce true to the parent variety. However, they seldom average equal in flavor to the selected varieties, which must be budded, as they are not reproduced true by the seed. Seedlings of the China are said to show a tendency to form an elongation of the rind at the stem, which makes them awkward to pack. In all cases where seedlings are to be used the greatest care should be exercised to select seed from isolated trees known to uniformly produce good fruit.

THE FLORIDA WAY.

In planting a citrus orchard, the land should be selected with great care as, while citrus trees do well on a great variety of land, they, like everything else, have their preferences. It is best, where possible, to select land that is naturally fertile, and particularly such soils as have a goodly supply of humus. If plant-food is deficient, it must be supplied in the form of commercial fertilizers and, if humus is deficient, by growing some covercrop to be turned under after it has died down.

Treating Lowlands.

Land that is low, wet and undrainable, or which is underlaid with hardpan, should be avoided. The same is true of extremely open, porous soils that do not hold moisture in sufficient quantities. Land for an orange grove should be moist, but of a character that is either naturally drained or easily drained artincally. Trees should never be planted on land where water stands for any length of time and becomes stagnant.

If the land is inclined to be sour (and a good deal of the virgin soil in the South is of this character), it should be well broken and cultivated for some time previous to setting the trees. If this is impracticable, it will be better to scatter over the surface, and harrow in, lime in sufficient quantities to sweeten the soil. Lime has the effect of making available the different plant-foods in the soil and taking out the sourness. From two to five barrels of air-slaked lime per acre will probably be sufficient. It is not a good idea to use lime except when absolutely necessary, as it has the tendency of too rapidly making available the plant-foods in the soil, thus quickly exhausting its natural fertility.

Handling the Trees.

Before setting citrus trees, trim back the tops well and then trim the foliage by cutting off two-thirds to three-fourths of each leaf. This reduces the rapid evaporation of sap that is always going on through the foliage, and makes success in transplanting much more certain.

Banking up oranges with fine earth in the fall is a great protection against cold. This also helps to hold newly planted trees against force of wind. Mounds should be removed in spring.

When trees are set, or just prior to that time, it is a good idea to mix with the soil that is to be placed about their roots about one pound per tree of some good, high-grade commercial fertilizer rich in ammonia. This puts fertilizer right where the roots of the trees will get it immediately as needed, thus forcing them to make a good first growth, which is always desirable. This fertilizer should contain about 4 to 5 per cent. of ammonia, 7 to 9 per cent. of phosphoric acid and 3 to 4 per cent. of potash, and should be made up with chemicals derived from mineral, not organic, sources.

Along in the spring, say about or early April, a second application of fertilizer, about one pound per tree, should be applied, and a third application during late June or early July is also advisable.

Cultivation and Mulching.

As the trees attain age and size, a larger quantity of fertilizer should be given and after they come into bearing a fertilizer containing more potash and less ammonia will be better. For this application to bearing trees, 10 to 12 per cent. of potash, 7 to 9 per cent. of phosphoric acid and 3 to 4 per cent. of ammonia is about right.

If the trees are transplanted during the winter months cultivation should commence about the time when growth ordinarily commences and should be continued until midsummer, after which time it is better to plant a sovercrop, like beggar-weed, in the middles between the trees. A small space immediately around the trees should be kept free from grass and weeds until later in the fall.

Mulching around the trees is practiced in some sections and is often advisable, as it serves to maintain a more equable temperature of the earth and retains moisture. After the covercrop has died down, in the late fall or early winter, it should be turned under, thus supplying humus to the soil and putting the land in beter mechanical condition. Covercrops sour and in poor condition for plant growth.

Another point in connection with covercrop or mulching, and this applies particularly to sections subject to damage from frost, is that all vegetable matter should be turned under in advance of danger from cold weather. A grove that exposes nothing but clean earth to the action of frost will go through the winter in much better shape than one covered with grass and weeds.—G. L. Taber, Glenn St. Mary, Fla.

Something Special

The finest Valencia Trees left in California are offered as long as they last for only $1.00 per tree. Price is lower and quality higher than others. Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

Bees and Their Care

KEEP BEES.

IN THIS era of diversification, the thought frequently occurs to me:

Why don't more farmers keep a few bees? I have asked the question of some of my friends, receiving the reply: Oh, I don't know anything about bees, or I would like to, but they sting so bad; or another will declare there is no money in bees, because his neighbor had some bees in boxes that he never gets any honey from. All this, and the numerous questions asked in these columns of your valued paper indicates that among the masses of the farmers there is little actual knowledge of the "busy little bee," the greatest living example of industry and economy.

There is no investment a farmer can make that will pay as high a rate of profit as a few colonies of good bees, say ten to forty stands according to growth of flowering plants or trees near by, provided he will handle them intelligently. By this I mean use proper equipment in the way of interchangeable hives, supers, frames, bee escapes, queen and drone excluders, a bee veil and a smoker. With anything like the care taken of their horses, cows, pigs or even the dogs, the bees will yield an average of 100 pounds of honey per stand per year. This is 150 per cent. profit, for it is all profit; the work is hardly worth counting, but do not misunderstand me; to get good results you must go at it right, get good bees, Italians or Carnolians preferred, on account of their gentleness. Use the standard Langstroth dovetailed hive which is made by all bee supply manufacturers, and use interchangeable frames throughout. A bee escape should be used on each stand to prevent the escape of the queen in swarming time. Queen excluders should be used to keep the queen from going up into the supers and making brood comb where only honey comb is wanted. A bee escape board can be used by those who are afraid of the sting so the bees can be driven from the supers down to the brood chamber when one wants to take out honey.

A veil is a safe thing to don whenever one goes around the bees. No honey should ever be taken from the brood chamber, for this is the storehouse of the colony.

Much valuable information can be obtained from the catologues of bee supply houses, as they tell all about their various kinds of apparatus, how to use and their merits. Before I went into the bee business I got all the catologues I could, then I studied them at odd times till I got some idea what to do and what to get.

If the farmer has no time or inclination to read and learn things, let his wife, son or daughter do it for him. By all means wake up and pick up the couple of hundred dollars going to waste every year on nearly every farm, especially in Texas, by overlooking "the busy little bee." I used to think I could not handle bees, in fact was "kind o' skeery of them," because when I was a boy a bumble bee would chase me across an 80-acre meadow to sting me, but I saw there was "money in it" so I tackled bee keeping and risked the stinger, soon found the stinger was about all booga-boo. (Not quite all) I am well satisfied in every way.—Farm and Ranch.

BLACK BROOD.

Our little friends, the honey bees, are, like other living things, subject to various diseases, some of which often have proven disastrous to the beekeeping industry in many parts of our grand country. One of the most dangerous of the bee diseases is what has become known as black brood.

A few years ago this dreadful disease very nearly extinguished beekeeping in the State of New York. At present notes of warning are being sounded by a number of the leading bee journals to the beekeepers to be on the lookout, as black brood again is lurking in many localities in many states. I therefore deem it my duty to also give a timely hint to the readers of this department. As I have myself fought a hard battle against this fiend, I know we are up against a stern reality wherever it gains a foothold, and it behooves every beekeeper to keep an eye on the brood in his hives.

Space is too limited to give a scientific discussion of the subject in this department. Bee journals and textbooks will give you information on this point. I can merely describe the symptoms and say what is to be done.

Here are the words by Mr. E. R. Root, who is an authority:

"Black brood is characterized by sunken and perforated caps of the sealed brood, but most of the diseased larvae die before ready for capping. The odor is not like that of foul brood (the odor of foul brood is much like that of boiling glue.—J. G. B.), but is more nearly that of sour, decayed larvae. The larvae, when first infected, have on the body a yellow spot, and move uneasily in the cell. After death they turn yellow, then brown, and finally black, ultimately drying down to a black scale on the lower side (cell wall). Unlike the scale of foul brood (which adheres tightly to the cell wall), this is easily removed. The ropiness, so characteristic of foul brood, is found only to a limited extent."

To diagnose positively some samples of the diseased brood, especially in the early stages, requires microscopic examination. All such samples should be sent to the Division of Entomology, Washington, D. C.

I would caution our readers to enclose all such samples in either wooden or tin cases, to conform to the United States postal laws.

TO CHECK SWARMING.

Probably the thing most annoying to the bee-keeper is the swarming habit. If the bees did not persist in dividing their forces so frequently much more surplus honey could be obtained, and the bee-keeper himself would feel more easy about his bees. In producing comb-honey in one-pound boxes it is necessary to actually crowd the bees into the section boxes, for they seem loathe to begin work in such small divisions, and this crowding is one of the incentives which creates the swarming fever. When producing extracted honey, abundant room can be given, and the swarming impulse is greatly checked. Therefore, if bees are to be kept far from the house, and cannot be given much attention, it is advisable to produce only extracted honey, which is done by giving the bees large combs and plenty of room, for it matters not whether the combs are entirely completed or not, as the honey is taken from them and the combs retained to be used.

TO PREVENT MOTH WORM.

The movable frame hive of the simplest make and Italian bees are almost a sure preventive against the moth worms. The movable frame hive gives the bees an opportunity to visit all parts of the hive, and the Italian bee is so much more industrious, and scatters all over the hive, that the moth miller has a poor show of entering the hive, and if she does, her eggs will more than likely be carried out, or should the egg hatch, the larva will be dispatched. A strong colony of any kind of bees is almost worm proof, but the Italians are the best.

If a colony loses its queen, or gets starved out and loses energy, the miller makes an entrance, and once they get into the hive utter extinction is sure to follow.

A frame hive is little better than a log gum or a box hive, unless it has a keeper behind it to look through once in a while.—W. F. M.

The heavy rains of the past ten days have very seriously damaged the plums and peaches in Placer county. The extent of the damage cannot be definitely stated, but it is known that fully 90 per cent of the Kelsey and Wickson plums and probably 50 per cent. of the Salway and Levi peaches are gone through failure to pollenate. Burbank plums and Elberta and Triumph peaches seem to be in much better shape. Other varieties seem to vary considerably in extent of injury.

The Vegetable Garden

By ERNEST BRAUNTON

TOMATO CULTURE.

TOMATOES, like many others of our cultivated plants, being the product of many generations of high culture and selection, must have suitable conditions for their development in order to be a profitable crop.

There is no doubt that more of the new and profitable varieties originate under average or medium conditions than in the extremes, either way. It would hardly be expected that a good variety would originate on very poor soil. Neither would this be likely to occur on very rich soil, because of the tendency toward excessive vegetative growth.

Since this condition would apply as well to the general crop, the aim should be to secure average conditions. Land that would produce from ten to twelve barrels of corn per acre should, other things being properly looked after, easily produce six to eight tons of tomatoes. This would be called average or medium conditions.

Almost any soil from sand to clay will produce good crops of tomatoes, but here again extremes should be avoided and, except under special conditions, such as where very early markets are to be supplied, it will be better to avoid the very light sandy soils. The soil must be in a good state of cultivation. Manures, fertilizers, lime and the growing of clover or other legumes all help to bring about this condition.

If a sod field is to be used, plow in the late fall or early spring and replow, cutting but a shallow furrow, in time to prepare for planting. Do not plant tomatoes on a piece of land which has had corn upon it the previous year, but rather let corn follow the tomatoes and later wheat or some other grain crop with grass and clover. Many farmers expect to get good tomatoes upon thin, sour land. Blight and disease in unfavorable seasons are always rampant upon such land and the grower becomes discouraged and is convinced that his soil is unsuitable for the crop, when, in reality, the failure is due to a condition readily rectified by the application of lime and manure.

BEAN BULLETIN.

The Department of Agriculture will soon issue Farmers' Bulletin 289, beans, prepared by L. C. Corbett, Horticulturists, Bureau of Plant Industry.

In this bulletin types of beans are discussed under Broad beans, Kidney beans, Lima beans, Dolichos beans, Soja beans, Scarlet Runner beans, and Velvet beans. These are divided into two classes, namely, Field and Garden beans.

Field beans are discussed under the following subjects: Preparation of the soil; planting, which includes the quantity of seed per acre, as well as depth of planting; culture; harvesting, which includes a description of the commercial methods of harvesting the crop by machinery; threshing, with a brief description of the types of machines used for this purpose, together with a brief description of the subject of cleaning and grading the product for market.

Garden beans are discussed under type of soils to which they are adapted, fertilizers used in connection with the production of this crop, cultivation, harvesting, yield, enemies and diseases. The whole matter is a brief summary of the commercial industries as they now exist in the United States of growing dry beans and garden or string beans. Maps accompany the text, showing the distribution of the two crops, and there are illustrations showing typical fields of beans grown for dried beans as well as those grown for string beans, together with character of implements used in handling these crops.

Copies of the bulletin may be obtained upon application to Senators, Representatives, and Delegates in Congress, or to the Secretary of Agriculture.

CULTURE OF ASPARAGUS.

If one is desirous of the earliest use of the bed, plants 1 or 2 years old can be brought from a gardener or seedsman, but otherwise the plants are easily started from seed. The seed is sown like any annual in drills 1 foot apart and 2 inches deep in rich, light soil, thinned to 1 inch apart when the plants are well started, and given frequent and thorough cultivation during the summer. When the plants wither, cut off the tops and cover the bed 2 inches deep with well rotted stable manure. The plants should be transplanted into their permanent bed the following spring, before growth starts. The permanent bed should be dug to a depth of at least 2 1-2 feet, and liberally enriched with well rotted stable manure thoroughly worked into the soil. The plants should be set with the crowns 4 inches below the surface, with the roots spread in setting, and the plants about 1 foot apart in the row, and given frequent cultivation, covering the bed with 4 or 5 inches of manure in the fall, after the tops have been cut off.

The following spring, and every spring thereafter, work a liberal supply of well rotted manure and 1 pound salt to each square yard into the bed before growth commences. The salt keeps down the weeds but is one of the best of stimulants for the asparagus. The shoots can be cut for the table with the beginning of the third season, though the growth will not be as heavy of course as it will be later. The shoots should all be cut, no matter how small, each time the bed is cut over, not leaving the spindling ones to run up to seed. Before cold weather sets in each fall cut and remove the tops and cover with rotted manure. Once the bed is well started it will continue equally productive for at least ten years, well repaying the minimum amount of trouble to start it, which is no more than is necessary to grow tomatoes or cabbage, that in their case must be repeated every year. Instead of classing asparagus as one of the difficult plants to grow, it should be considered the easiest.—A. B.

CUCUMBER LICE.

This pest destroys many hundred acres of cucumbers and melons each year. Every grower of these vegetables should make a study of exterminating this insect, as it means the success or failure of his entire crop.

There being a foundation for all things to build on, so there is one most important basis from which to work in destroying cucumber lice.

The grower should procure from a reliable seed house his seed of the best quality, seed that have been grown under climatic conditions best adapted to their fullest development, the plants having been free from lice. He will then secure a stand which is healthy and more able to withstand the attacks of insects.

If the grower wishes to be on the safe side, he should spray his entire crop with kerosene emulsion before the lice have appeared. Then spray the second time in about ten days. This will almost insure his crop against these bugs.

Should the lice appear he should go over his field and pull up each infected plant and burn it at once. Then spray his entire field with kerosene emulsion, using a goose-neck nozzle in order to reach the under side of the leaves. If this is done deliberately, the grower will soon rid himself of this pest.

To make kerosene emulsion, take of good hard soap (in fine shavings), one-half pound; soft water, one gallon; kerosene, two gallons.

Dissolve soap in boiling water, add the kerosene to the hot water, churn the mixture with spraying pump until it changes to a creamy, then to a buttermilk moss color. This gives three gallons of 66 per cent. of oil emulsion, which may be diluted to the strength desired. Add ten and one-half gallons of soft water to this amount to make 15 per cent. kerosene emulsion. This strength will give the best results.

Kerosene emulsion has given the best results of any exterminator known. In fact, it is the only sure way for a cucumber or melon grower to be successful if his crop is attacked by these insects.—C. W. R. in Southern Fruit Grower.

CORN CORN CORN CORN

Plant Eastern-Grown Seed Corn

Johnson & Musser Seed Co.

Up-to-Date Seed House

Iowa Silver Mine, Grown on the Rosemead Ranch by James Gooch from our Eastern-grown Seed.

We have just received our usual carload of Nebraska-grown hand-picked Seed Corn, and offer it at the following prices f.o.b. Los Angeles:

King of the Earliest, 85 days. The earliest Dent variety. Ears short, 12 to 16 rows, well filled. Grain long and yellow, making an extra quality meal. per lb. 5c; 100 lbs. $3.50.

Improved Leaming, 90 days. Ears are large and handsome, with deep, large grains; orange-yellow color and red cob. Per lb. 5c; 100 lbs. $3.50.

Pride of the North, 90 Days. One of the best sorts; ears have from 14 to 16 rows 8 to 10 inches in length, slightly tapering; color light orange. Per lb. 5c; 100 lbs. $3.50.

Minnesota King, 100 Days. A large-grained variety; yellow. Per lb. 5c; 100 lbs. $3.50.

Wisconsin White Dent, 90 Days. A perfect white Dent corn, of good quality, resembling the Leaming. Per lb. 5c; 100 lbs. $3.50.

Champion White Pearl, 90 Days. A fine white flint corn. Per. lb. 5c; 100 lbs. $3.50.

Early Mastedon. Having grown and sold the Early Mastedon corn four years, we recommend it as being decidedly the best of all Yellow Dent varieties. Every one who has seen it grow is enthusiastic in its praise. Large ears, deep grains, and as many as 24 rows on a cob. Eastern grown, per 100 lbs. $3.50.

The Iowa Silver Mine. A large White Dent. The grains are as large as the Hickory King, but longer, having a small cob. It is the most desirable of all White Dent varieties. Per 100 lbs. $3.50.

Red Cob, Ensilage. A large stalk with a profusion of leaves which makes it the most desirable for ensilage. Price, per 100 lbs. $3.50.

Stanford White Flint. An excellent White Flint corn. More prolific than the King Philip. It is an excellent extra early table corn. It has long ears and a small cob. Price, per lb. 5c; per 100 lbs. $3.50.

White Cap Yellow Dent. Exceedingly prolific and hardy, resisting drought much better than other varieties. Per 100 lbs. $3.50.

Reid's Yellow Dent. This is the variety that has been brought to a high state of perfection by the Illinois growers, and drew the medal at St. Louis because it averaged the greater number of pounds per bushel. Price, per 100 lbs. $3.50.

King Philip, 90 Days. A small yellow variety, very popular in this market. Price on application.

Hickory King, 110 Days. A white variety, having the largest grain with the smallest cob ever introduced in a white corn. Price on application.

DEATH RATE OF THE FARMER.

A writer in Harper's Weekly makes the statement that the average death rate in this country is the highest among the laboring classes, being 20.2 per thousand. Farmers come next with 17.6. Merchants and traders follow with 12.1 per thousand, and clerical and professional men average 13.5.

The mortuary tables of life insurance companies place the farmers next to professional men in death rate, and explain the singular phenomenon on the ground that, as a class, they are less careful of themselves, oftener subject to exposure of the elements, without precaution as to health and less regular about observing the laws of cating which are so essential to longevity. In the table furnished by the writer of the article in Harper's Weekly, he places the death rate of the laborer at 65 per cent higher than that of business men and farmers, 45 per cent higher than business men.

The singular part about this statement, is the fact that the writer attributes as a cause of the high death rate of the laborer and the farmer two conditions, viz.: overwork and insufficient feeding, and he urges as an element, to change the death rate, that laborers eat more and rest more. It has generally been supposed that farmers are among our best fed classes, but it seems that they are not, although from what reason we are unable to say.

Commenting on the statement made in Harper's Weekly concerning the death rate in the laboring class, the Journal of Agriculture remarks: "It is easy to see how it might be true of the laboring classes in cities, but how it applies to farmers is hard to understand. Everybody will admit that farmers work hard, but of all classes of people, they certainly get plenty to eat. Still, we will not dispute the author's statement, and if it is true we are willing to regulate ourselves accordingly. Less work and more to eat is a motto that will appeal to nearly everybody, and if it can be lived up to, conditions ought to be ideal, both on the farm and in the city. While he was about it, though, we wish the writer had told us just how we can exist by following such a rule. We can get along all right on less work, but that generally means less to eat. However, as this is about the only life most of us will have a chance to live, we should make the most of the advice given us. The sum and the substance of it all is that the world is living too fast and the sooner we put on the brakes, the slower we will be to die."

We believe irregular eating, and over-eating, and too rapid eating, has more to do in killing farmers than under-eating. In fact, we don't believe in the theory of under-feeding in the case of the farmers, who certainly have opportunity to eat if any class has, but we know, both from observation and experience, that the farmer is the most irregular eater of any class of laborers.

He comes to his meals late, oftener than otherwise, is tired, bolts his food in a hurry, and is back at his work giving his body no rest either before, during or after his meals.

In a few years his digestion is impaired, his food does not assimilate, disease finds lodgment in his body and he succumbs before his time. We all know that regularity in eating conduces to health and strength, and if the farmer will give himself time to eat, and eat at regular hours, he will lengthen out his life. He eats enough, but he does not eat right.

APRIL PLANTING.

In general, especially in seasons of unusual rainfall, our orchadists prefer April as a favorite month for orange tree planting. Many successful growers contend that it is the best month of all, but they insist that in all cases where it is possible, whether the trees are to be balled or moved with naked roots, it will be best to dig down on one side and cut the tap root, fill up the hole again and let stand for two or three weeks until the cut roots have time to heal over. In this way success is more assured.

In this present time of high prices for orange trees, the tree digger is being resorted to for orange stock, and if the digger can run through the nursery rows, cutting the roots and let stand for a week or two and then moved, they will bear transplanting much better, but in all cases of moving with naked roots they should never be allowed to get the least dry, but should be immediately puddled and kept shaded until planted, and irrigated as soon as put into the ground.

Work will continue to crowd the thrifty orchadist, for what, between keeping weeds down and cultivating the soil with a view of conserving the moisture therein, as well as increasing it by letting the warm, moist air penetrate to have its moisture condensed in the soil and stored for future use, the planter of new orange groves will find his time fully occupied.

WANT ROOSEVELT.

If we are to take the expressions of prominent men of both the great political parties of the country, as voiced in the newspapers, the people are in favor of the renomination of President Roosevelt. They want him to complete the Panama canal. They want him to finish his debate with Harriman and to squeeze the water out of the railroad stocks and bonds. They want him to teach Wall street honest methods of business. They want him to purge our great cities of graft and thievery. They want him to teach men that to water stock to thrice its value, is a crime punishable by penitentiary sentence. They want him to stop the manipulation of stock and bonds in corporations that bring ruin to thousands of business men and induce crime and suicide. He is what people call "straight goods," honest enough to enforce honesty among corporations and courageous enough to fight for principle, no matter who is hurt. Roosevelt is the reformer of the age, who Bryan says he may yet nominate for his own successor.

Really, political affiliations of individuals seem to be giving away in one overwhelming demand for Roosevelt's renomination. The insurmountable obstacle to this end seems to be the President himself.

THE ORANGE OUTLOOK.

The happiest man today in California is the orange grower. He looks over his grove and he counts his sheckles, real yellow ones, as yellow as the luscious fruit itself, by the thousands, provided he has acres enough to warrant such figuring. Since November first almost 14,000 cars of citrus fruit have been shipped and the grand work goes on. Last year to this date, over 16,000 cars had been shipped, but the transportation facilities were better, which let out about 2000 cars more than have gone this year to date. But this shortage will not be seriously felt for prices are good, the demand is excellent and the future is full of promise for the orange industry.

Oranges have come to be a necessity on the breakfast table of the Easterner, whether he be rich or only partially so. Lemons, of course, have always been a staple product, and the more people come to know their value, as health restorers and health keepers, the greater will be the demand for them. So the lemon grower takes no back seat to any industry in the state but goes merrily on harvesting his crop, and coining his money like a banker.

The fear many orange growers felt a while ago that during April their fruit would puff has not been realized; the fruit, although large, was never surpassed for juiciness nor sweetness. The fruit is arriving in the Eastern markets in fine condition, which gives it a delightful appearance and entices the housekeeper to purchase it whether she feels she can afford it or not. Prices have so far been good on the average, and the prospect now is that they will remain good throughout the year.

OUR AGRICULTURAL GROWTH.

The Department of Agriculture will be elaborately represented at the Jamestown Exposition, to be held this year on the banks of Hampton Roads, in Virginia. To this end the exhibits of grains, grasses and improved farm appliances will show the growth of the country along this line for the past quarter of a century. In addition exhibits of manufactures, industries and inventions will be selected, and the visitor will be greatly impressed with the graphic representation of the growth of the nation, from its humble beginning through the various stages of its development, to its present grandeur.

The industrial display will be classified in such groups as Manufacturers and Liberal Arts, Machinery, Transportation, Mines and Metallurgy, etc. Under the head of manufactures will be exhibited hardware, furniture, watch and clock making, textiles and many others. Under the head of machinery will come a great display of steam engines, various motors applicable to farm work, general machinery and machine and arsenal tools. So on down under the various departments will be exhibited all the industries of the country, in a concise and intelligent way.

BRYAN'S R. R. PLAN.

Mr Bryan has been giving his government railroad ownership scheme some further advertisement, by developing it in detail in a letter to a friend in Boston. In this letter he says he is in favor of "both National and State regulation, and also believes that public ownership is the solution of the railroad question."

In order to overcome the danger, as he sees it, in centeralization in ownership by the Federal government of all the lines, he prefers a system in which the Federal government will be confined to the necessary trunk lines and the ownership of the rest of the lines be left to the states.

"As an advocate of regulation of the strictest sort," says Bryan, "I can say to you that there is no danger whatever that this regulation will be carried to the point of preventing a reasonable return on money invested in the railroads of the country. And I also assure you that whenever public ownership is adopted by the states or by the nation the stockholders may expect to receive a price at least equal to the value of the physical properties of the road, but no such assurance ought to be necessary, because the public has shown no disposition to reduce railroad earnings to a point which would deny a reasonable return."

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Alfalfa will soon yield its first crop at Little Rock.

The San Joaquin Fruit company has begun planting peanuts and is keeping two planters steadily at work.

Wheat and barley in the Antelope valley sown this spring is looking fine. A good crop is expected.

During the past two years the business of raising turkeys has become an important industry in the Imperial valley.

The Duarte-Monrovia Fruit Exchange has declared a dividend of one cent a pound on fruit shipped in March.

The Imperial valley farmers are now shipping string beans at 25c per pound and summer squash at 12½c per pound.

By May 1st a great many tomatoes will be shipped from the desert. There is a large acreage in and the price bids fair to be good.

The output from the Thermal packing house this season will be 75 cars of melons, five cars of grapes, 60 cars of onions and 18 cars of cabbage.

The express shipments for the week were 247 cases eggs, 1217 pounds of poultry, 1195 pounds of butter and nearly two tons of cream from Escondido.

About Thermal the valley is in a very prosperous condition. The farmers are now busy shipping onions, which are bringing a good price this season.

Kuhl & Paul, of Coachella, ran a close race with J. W. Leonard of Thermal, in shipping first string of green beans. They shipped April 12th and received twenty cents net.

Joe Hanson, on the 13th, started his harvesting machinery on his ranch near Imperial. This is the first harvesting to be done this season in the valley and probably in the state.

The alfalfa farmers of Chino held another meeting April 9. There was a good attendance and a rousing interest manifested. It was agreed that prices as previously fixed should stand.

Last season many thousands of turkeys were shipped to Los Angeles from Imperial, but with all raised in this state several carloads of the dressed birds were shipped from Kansas.

Twenty or thirty acres of summer squash are now ready for the market at Thermal. Ten or fifteen acres of cucumbers are doing finely and will be ready for shipment within a few weeks.

The first car of Bermuda onions of the season from Thermal was shipped to Los Angeles Tuesday. They were sold f. o. b. there for $1.95 a crate, which brings to the grower about three cents a pound net.

Crops around Beaumont look well, but more rain will be necessary for good results. A medium rainfall for this vicinity is better in a general way than excessive rains, such as we have had this winter.

The dairy business of the Lompoc section has been making rapid strides this past year. There is shipped from this station $9000 worth of cream every month. Most of this goes to Santa Barbara and Los Angeles.

The setting out of young orchards in the south is now over for the season, and despite the prediction of many growers of an overproduction of fruit, there has been a larger planting of deciduous fruits than ever before.

Reports come in from most of the grain growers of the Rialto section that the indications are that the crop will not be as heavy as last year. The cause is attributed to the excess of rain this winter, combined with the unusual amount of cloudy, cold weather.

HORTICULTURE.

Redlands has a lemon club.

The strawberry harvest is on at full blast at Villa Park.

Pine scale is bad on trees about San Bernardino, especially on the Monterey pine.

No doubt now about pears and apples being a paying crop about Little Rock this year.

The La Habra Walnut Grower's Association filed its articles of incorporation last week.

The almond crop about Fairmout has suffered severely by the recent frosts. All except E. W. Spencer's are gone.

The apple crop in the hill ranches back of Fairmont will be a banner one, reports were never so favorable as they are this year.

An authentic report of a ten-acre orchard at Ontario last year states that the fruit netted the owner $5000 after all expenses were paid.

The apricot crop in Orange county will be almost a failure as the last rains have rotted what the earlier rains did not prevent setting.

There has been heavy planting of apricots in some sections while in the apple sections there has been great activity in the setting out of that fruit.

There are still about 600 cars of navels to be sent out from Redlands this year, and at the rate maintained last week it will require four weeks to do it.

Tuesday the Pacific Packers' Supply Company received the first carload of its special machinery for the new box factory which is to be located in Redlands.

Redlands packers are taking the lead in protesting against the new order for car distribution which went into effect on the Southern Pacific last week.

In deciduous orchard planting, peaches have led by long odds, and chief of these have been cling varieties. This is largely attributable to the cannery demand.

A car of thoroughly-cooled oranges, packed in a car also pre-cooled, was sent East from Riverside today to test the practicability of shipping California fruit without ice.

With one exception the past week has witnessed the largest movement of oranges from Redlands of any week this year, there being 174 cars of 362 boxes each to be forwarded.

The Pacific Packers' Supply Company which owns the patents on the rawhide pulpboard boxes—has received the first carload of machinery for its factory at Redlands.

The State Insectry, which has been maintained at Anaheim the past month, was moved to Los Angeles and will continue introducing the newly-imported red and purple scale parasites.

Instead of the ordinary load of 384 boxes of fruit, the fruit contained in a pre-cooled car is 549 boxes. This extra amount of oranges to the car was made possible by the elimination of the ice chamber.

Hemet will have a very good crop of apricots this season, and already buyers are numerous offering fifty dollars a ton for the fruit. Reports are most encouraging for a good peach crop this season also.

Several carloads of Mediterranean Sweets, St. Michaels and blood oranges are shipped from the Hemet Packing Houses every week now. The fruit is absolutely without scale, is perfect and brings high prices. The navels, of which there was a fine crop, have all gone forward at fine prices.

Peaches about Santa Ana have bloomed profusely and indications are good. Pears show an extraordinary healthy bloom. Apples are blossoming. Grapes are starting. Walnuts are coming out very rapidly and are so early as to be considered dangerous for blight.

Northern California

AGRICULTURE.

Good rains in the Lakeside country Sunday make the farmers rejoice.

The poultry business near Pleasant Grove is fast becoming one of the leading industries.

The hop growers of the state are watching with keen interest the effect of the law governing their sales.

The report that the fruit crop was ruined by the recent heavy storms is untrue so far as the Uvas valley is concerned.

The registered Holstein-Friesian bull Loyal Knight of La Siesta was sold last week to F. H. S. Hersman, San Martin.

Bill Whyler, of Willows, drove 250 hogs on the scales and found that they averaged 250 pounds per head, and brought him $4375.

During the month of March Elmira farmers shipped by express 6494 dozen or 77,928 eggs and 72 cans or 5,250 pounds of cream.

P. B. Norton, the U. P. railroad representative has a quarter section of land south of Remnoy which he is planting to eucalyptus trees.

The crust has become so hard on the grain land about Salinas, that some of the farmers on the uplands have stopped plowing until it rains.

Barney Schrieber, who recently leased the Howard farm near Woodland, received a carload of horses Monday, followed by another carload on Wednesday.

Old Tulare lake is coming this way, the little blue waves are now lapping ground that has been untouched by old Tulare for over a quarter of a century.—Visalia Times.

Yolo county, especially that part of it lying closely contiguous to the city of Woodland, is rapidly becoming a favorite field for men engaged in the business of raising fine horses.

A gentleman from Lemoore stated Friday that Frank Blakely, who has between 2000 and 3000 acres seeded to wheat and barley on the borders of the lake, has a fine prospect.

The sheepmen of the state are getting anxious to have Governor Gillett appoint a State Board of Sheep Commissioners, as provided by an act which he signed and which is now a law.

George Gottwals of Central District sold two big hogs which weighed 780 pounds or nearly 400 pounds each. As the price was 8c per pound Mr. Gottwals received over $30 each for the same.

The Bank of Willows has deeded to the Glenn County Irrigated Farms Company 1020 acres of land east of Willows, which will be subdivided and placed on the market in small tracts.

Early-sown summer-fallowed grain about Woodland looks splendid, winter-sown grain is growing nicely and alfalfa is growing so luxuriantly that bumper crops are predicted, so says the Democrat of that place

That California can easily produce all the hemp that the world needs is the opinion of R. J. Shely, of Chicago, who is now in Sacramento valley looking over the prospects of establishing the industry.

The present unfavorable season for grain is giving added impetus to the tendency now prevalent among the farmers in the vicinity of Elmira and on the plains east of Vacaville to go into stock raising and dairying.

There will be but little grain raised in the valley around Woodland. One farmer who usually sows 1000 acres of wheat and barley seeded only about 200 acres this season. Other grain farmers seeded about the same proportion.

The following pedigreed Holstein cows were transferred last week: Circuela 2d, C. W. Evans to M. H. Holdridge, Modesto; Clio of San Martin, Frank H. Burke to H. S. Hersman, San Martin; Eulalie of La Siesta, Frank H. Burke to H. S. Hersman, San Martin.

HORTICULTURE.

The recent storm nearly ruined the almond crop in the upper Capay valley.

An active campaign has been going on in Sacramento county against pear blight.

Over 100 cars of oranges have been shipped from Lindsay since the first of the year.

The tent caterpillar has begun to make its appearance in the orchards of the Pajaro valley.

The Falke place, west of Redding, is to be converted into a first-class garden and poultry farm.

Experts say the apricot crop about Grinda is damaged. Peach and almond crops will also be short.

The unusual rainfall has, in many fruit growing districts, aided the development of fungus tree diseases.

Water standing in orchards is doing serious damage in some parts of the San Joaquin and Sacramento valleys.

The damage to fruit trees in the mountains and in the foothills about Los Gatos has been greatly overestimated.

J. P. Cox is erecting some stable buildings at the "villa," near Orangevale, preparatory to starting a breeding farm.

There is at present fair prospects for an average fruit crop in Sutter county with the exception of almonds and apricots.

There are nearly 2500 condemned blighted pear trees on Tyler and Andrus islands where the water is standing in the orchards.

Prunes and apples about Gilroy will be a better quality and price. Grapes were not in blossom, so consequently were not injured. Peaches will be an average crop.

The pear crop about Woodland, from present appearance, will be unusually large. The prospects are also good for an average crop of both prunes and plums.—Democrat.

The result of last year's campaign against the caterpillar in the Watsonville district is very evident in the decreased number of caterpillars coming into existence this year.

French prunes and Bartlett pears about Vacaville look promising, the peach crop is very light; the apricot crop is a failure, although there will be a few more than last year.

The crop of early peaches in Yolo county will be light, but there will be big crops of the late varieties. The heavy rains destroyed a great deal of the bloom of the early crop.

In the district comprising Grand, Tyler, Andrus and others, where owners were delinquent in the eradication of the pear blight, 30,000 trees were inspected with a loss of nearly 4000.

Governor Gillett is quoted as saying that he will go to Washington next winter and press the claim of the Sacramento river before the rivers and harbors committee for an appropriation of $400,000, as recommended by the federal engineers.

The peach orchards north of Sacramento that have been sprayed thoroughly and given good care show a fine prospect and prunes, cherries and pears have bloomed well and the fruit is setting good. Almonds will not be a quarter of a crop from the present outlook.

Excellent results have attended the campaign against the pear blight in Sacramento county, which began last winter and closed with the recent storms. Although the blight has not been thoroughly stamped out, as might have been the case had all the orchardists shown a ready disposition to co-operate in its eradication, the county commissioner considers it encouraging.

The Capital Avenue Poultry Farm, R. Walker Mantz, offers some special inducements in White Wyandottes and Columbian Wyandottes to their patrons in their advertisement this week.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.

"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clork Exposition."

Chicks Just Hatched

We ship them everywhere. Pure Bred White Leghorn Chicks from the Best Egg Producers in the United States

CALIFORNIA INCUBATOR CO., MAXWELL, MAY 27, 1906.

Gentlemen—The little chicks arrived in perfect condition. It is very remarkable that 600 little fellows would come so far and being so long on the way without the loss of a single one, but it is an undisputed fact that such was the case. We are thinking of getting a few more providing we can get them right away. Answer by return mail. Yours truly, J. F. CAMPBELL.

CALIFORNIA INCUBATOR CO., 907 Washington St., Petaluma, Cal.

Profit in the Poultry Yard

By Mrs. A. Basley, Hollywood, Cal.

COMMERCIAL PIGEONS.

"I used to keep pigeons when I was a boy," writes a middle-aged man, "and I would like to try again. Can you give me any information on the subject?"

The writer goes on to ask many pertinent questions on the pigeon business and I think that the following from the pen of Mr. R. S. Ransom, who is making a comfortable income from pigeons raised in his own backyard will give our enquirer the information he seeks.

The amount of misinformation given on this subject is simply appalling. Why is it necessary for some people to grossly exaggerate anything said or written about Homer squab raising, when the plain, unvarnished truth presents the matter in a most favorable light. It is true that as an industry, squab raising requires less capital and less work in proportion to returns than any other business of similar character. It is not right to lead people, as some do, to believe that all that is necessary is to buy a miscellaneous lot of pigeons, place them in lofts, feed and water them regularly, and sit down to wait for the coin to roll in. The individual who embarks in the business of raising squabs for market with such an idea, is doomed to failure from the start. "My advice to the beginner would be," says Mr. Ransom, "Don't go into the business; grow into it." Make a beginning with a reasonable number of birds in order that you may know absolutely that they are properly mated when placed in the breeding pen, and that you may have an opportunity to study the birds and their habits, as your flock increases. After you have acquired sufficient pigeon knowledge, you can begin selling squabs, and from the revenue thus derived, buy additional breeders, being careful to deal only with those whose stock is equal to or better than yours. This point cannot be too strongly emphasized.

If you contemplate having a loft, you will want birds that will produce from eight to ten pairs of squabs a year, and not old played-out stock that may give you from two to four pairs or may not have fertile eggs.

In order to protect yourself in this particular, buy young and healthy birds from breeders of reliability and responsibility. Experience proves that young birds just mated are far preferable to "old mated birds," that have worked for months or years in a certain loft to which they have become attached. The old birds in many instances, will mope and pine for the old home, while the young birds will go to work without delay.

Now as to the birds best adapted to the work of squab raising, the most prolific bird and the best feeder is the Homer pigeon, and a carefully selected loft of these superior birds will show their owner an average annual return of eight pairs of squabs per year for each pair of breeders. It costs in this locality, about $1 per year to feed a pair of breeders. As the squabs are ready for market when four weeks old and sell for at least $3.00 per dozen, the reader can easily figure the profit. In this connection it should be borne in mind that unlike chickens and turkeys, the feeding of young pigeons is attended to by the parent bird, thus saving a great deal of time, trouble and attention which, in other branches of poultry raising, must be looked after carefully by the individual in charge of the plant. It seems that the pigeon has never reached that stage of thorough domestication where the young birds may be fed artificially, but like the wild birds of the forest, the pigeon is one of the few domestic fowls that attend to the feeding of their young, the first week with what squab raisers call "pigeon's milk," and then grain until they are old enough to shift for themselves. Thus one of the most troublesome parts of chicken raising is absent in pigeon culture.

The main advantages of raising Homer squab for market over the squab of the common pigeon and other poultry are these: Less competition, less trouble in attending to the young, for the old birds do all the work, larger squabs and more of them, which means a better price and more frequent sales, and when a pair of pigeons are once firmly mated they will remain so and do well for ten or twelve years unless separated by accident or disease. From a pair of first-class Homers, you can depend on raising from eight to ten pairs of squabs per year, which can be marketed at the rate of fifty cents per pair dressed, while the cost of feeding the old birds will not exceed one dollar. Pigeons lay two eggs for a setting; one day intervening between the laying of the first and second egg. The incubation requires about 10 days, and while attending to the young in one nest (there should be two nests in the loft for each pair of breeders) they generally build another nest and have eggs before the young are capable of taking care of themselves. The birds breed all the year, except during the molting season, which occurs in September and October.

The first thing connected with a business of this kind is to have good quarters for the birds. This does not mean anything expensive. An idea of the space required may be had from the following: A room ten by twelve feet and six feet high at the eaves will accommodate 40 to 50 pairs very nicely, which will be enough to keep together in one place, as too many birds kept together complicate matters. This number is all a beginner

should start with, and should not be increased until the birds and their habits are learnt, and some knowledge of the business is gained.

Pigeons besides requiring room must have plenty of fresh water. They want a good supply not only for drinking, but for bathing, which they much enjoy. They also need grit and cracked oyster shell to aid digestion and to form the egg shell; salt, and occasionally charcoal. All these keep the birds in health, without them they become sickly and die. More pigeons die yearly from lack of grit to digest their food than from natural causes. Almost all diseases of the pigeon originate from some neglect of the owner. Homers are good breeders, are a good paying stock to have, as they require less attention than chickens, but to secure the best results from any flock, the birds must have proper attention.

If you contemplate raising squabs on a large or small scale, write to the Department of Agricultural, Washington D. C. for a copy of Farmers' Bulletin No. 177. That publication treats fully and fairly on the subject of squab raising. This Government publication can be depended upon, as the most reliable work issued on the subject. If, after reading you decide to engage in the business, buy your birds from some breeder upon whom you can depend for an equal number of males and females. There are persons in Los Angeles whose experience in this respect proved mostly costly and vexatious.

CARE OF THE SITTING HENS.

It is well to see a number of hens at one time as near together as possible for two reasons: 1st, so that after testing the eggs the sterile ones can be replaced by fresh eggs and thus save time and trouble for the poultryman.

Also as a means of getting more chicks from the same hens than would otherwise be got if the eggs were not tested. The second reason is that they can all be attended to at one time with little or no more care than attending to one broody hen. It is a good plan to keep the sitting hens closed up so that they will be kept dark and quiet.

Following out this plan it will be necessary to take the sitters off every morning, feed and water them, and then see that they return to their proper places and are closed up again until the same time next morning. There is a certain way broody hens should be fed. What? Whole grain, a little water and some grit.

Don't allow them to drink all the water they need and don't feed soft feed. Both of these will keep them too open, and it is not a good thing for a sitting hen that can only get off the nest once a day.

The day has arrived for the chicks to come out. How are you going to receive them? Some hens are very restless when hatching and are liable to kill some of the chicks.

In such cases it will be well to take them away from the hen as they hatch without disturbing her, and place them in a basket of flannels near the stove, so as to keep them at about the same temperature as the body heat of the hen.

Here they can be kept until the whole hatch is out, when they can be given back again to the mother hen. Then she should be put into new quarters. Under no circumstances should she be allowed to take her brood to the nest, for if she does she will be sure to kill some of them by trampling on them. March is generally a windy, unsettled month so the poultryman had better prepare for this kind of weather, for it will surely come sooner or later.

If all the hens hatch at once, as I have suggested, 15 chicks can be given to each hen, and some of the others without chicks can be set over again, if well cared for. Where is the best place to put Mrs. Hen with her brood? There is no better place than a nice pen facing the south so that they will get all the sun there is to be had. They must be kept in a warm place, otherwise they will not grow; on the other hand they will linger on and eventually die. Keep them warm and dry. These two things are very important.

Nothing is better than a board floor

DON'T FEED the little chicks anything for the first twenty-four hours. Then feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seed, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it all up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. For sale by many dealers. If yours does not keep it, try another, or send to us and we will see that you are supplied.

kept clean. If it is sprinkled with fine sand they will get all the natural grit they need. March chicks are early chicks and come into existence at a time before Nature intended they should. They therefore must receive special treatment.

Another question that arises is, "How are they to be fed?" For the first twenty-four or thirty-six hours of the chick's life it should not be fed anything. Nature has provided for it during this time. At the end of this time begin feeding. What should be fed? There are many things.

A favorite food is hard boiled eggs chopped fine, mixed with stale bread crumbs. Feed only a little at a time and often so that when they are fed their feed is always clean and sweet. This should always be the rule in feeding young chicks.

A fault too prevalent in raising chicks is to feed too much at a time, so as to avoid tending them so often. This is a great mistake and a mistake that brings on diarrhoea. Nothing will bring on diarrhoea quicker than eating dirty feed.

The poultryman who has early chicks wants to force them. This can be done by giving them milk, sweet milk to drink instead of water. There is a lot of nourishment in it and it will serve as a food and a drink at the same time. Keep them clean and dry if you can. If you can induce them to scratch in a nice warm place the rest will be all right. They will grow if fed well; feed a variety.

Chicks soon get tired of the same kind of food. Feed greens of some sort, chopped fine, bread and milk, egg, stale bread crumbs, little bits of cooked meat, a little mash, corn cake, or what some of us Scotch folks call Johnny cake. All these things are good for the chicks at any time, but especially so during the month of March when they cannot get out on Mother Earth to pick for themselves. —Edw. Wyatt, in Poultry Journal.

HATCHING LEGHORN HENS.

I made a number of incubator hatching tests one time that demonstated some points in artificial incubation that I have never seen in print, viz:

That Leghorn eggs will make a good hatch on lower temperature than it takes to hatch Plymouth Rock or Brahma eggs. I know exactly what I am talking about in this instance.

My tests proved it beyond my expectations. My expectations were gathered from the nature of the fowls and the difference in the size of eggs, also from little points gathered through observing the results in making hatches on mixed eggs.

My test was made with six 100-egg incubators. They were made exactly alike and all run alike in the same room and under exactly the same conditions. Before starting, I tested the therometers to make sure that there were no fractions in differences.

I set three machines with Brown Leghorn eggs and three with B. P. Rock eggs. I set each machine three times. The test was made in the months of May, June and July. Ran the temperature on the Leghorn eggs in one machine 101 and 103, on another at 102 to 104, and on the other at 103 to 105. I duplicated the plan on the three machines filled with Plymouth Rock eggs.

The lower temperature made the best hatch on Leghorn eggs while the higher temperature made the best hatch on Plymouth Rock eggs. For the second test, I reversed the machines; that is, I took the one that had been run on the higher temperature and ran it on the lower temperature, made this reverse with both sets of incubators.

The results came out as before. The higher temperature made the best hatch on Plymouth Rock eggs, while the lower temperature made the best hatch on Leghorn eggs. With the Plymouth Rock eggs there was only a small per cent. in favor of the higher temperature. The third trial emphasized the results. This is the first time I have ever spoken of these particular experiments.

I made the experiments to test an idea formed while watching incubator results on different kinds of eggs and through studying the nature of the sitting and non-sitting varieties of poultry. I am thoroughly convinced that there is fully one degree difference between the right temperature for Leghorn eggs and the right temperature for Plymouth Rock or Brahma eggs. My conviction is that that two degrees difference between Leghorn eggs and Brahma eggs is about correct.

It is the experience of all incubator operators that Leghorn eggs hatch a day earlier than Plymouth Rock eggs in the same incubator. The same thing invariably happens in a hen's nest, yet a Leghorn that will set on her own eggs will hatch in 21 days, and the same of the Plymouth Rock.

On the first thought, the difference in temperature seems queer, but if we extend the thinking and reasoning, it is not so queer, after all.

It is a fever that makes hens broody. The larger varieties are more inclined to broodiness, the fever is higher.

With the large body, the heat is greater in proportion to the feathers. It is a hard matter to find opportunities to take the temperature under a setting Leghorn. Only once have I ever been able to do so on account of the wilder nature and the sensitiveness in having things other than eggs under her, but in the one good test the temperature showed 102 on the eighth day.

On the other hand, I have known the temperature to show as high as 106 on the twelfth day under a Plymouth Rock hen. In dozens of tests the thermometer has shown 104 after a week's incubation under the larger varieties. Let me further say that as a general rule the best results are obtained with incubators with a degree higher temperature in a cold room than in a warm room. This difference is due to the bottom of the machine being cooler in a cold doom. —Farm and Ranch.

RHODE ISLAND REDS

What breed of chickens are the best winter egg-machines? Eggs are what poultry people want when they are scarce and high priced.

The question has perplexed me no little. Two or three years ago I began to look about in order to find the most practical breed to adopt, having learned from experience that eggs for market was our greatest source of revenue, and paid us best of anything we sold, especially winter-laid eggs.

I began with the pure-bred light Brahmas. I thought they were good winter layers and after losing their usefulness as layers would make an ideal market fowl. They did not. I soon found they would not serve my purpose well, so I brought in a flock of brown Leghorns. They did better, but both breeds layed more eggs in summer than in winter.

Then I went for a pen of Barred Plymouth Rocks. They did reasonably well, but I was not satisfied with them entirely, so one year ago I bought six Rhode Island Red hens and one cockerel. Two hens did not do well—took cold in shipping.

From the four other hens I raised 125 as nice fowls as you would want to see. They grew faster and matured earlier than the Plymouth Rocks, all receiving the same treatment. They began laying earlier and are still away ahead in number of eggs. Twenty-eight Reds are now laying more eggs each day than seventy Plymouth Rocks, all treated and fed alike and being the same age.

This fact has settled me on this breed, and the present year I expect to raise enough Reds to keep them exclusively.

Every pullet that proves to be an early and good layer I will reserve for breeding, and by this method of selecting the best layers for breeding and mating them to cockerels from heavy layers, I expect to build up a family of layers that will give me a profitable number of winter eggs.

I will be careful to select birds for breeding that are vigorous and that conform as much as possible to standard requirements. I believe that the selection of the male bird that heads the pen is of as much importance as the selection of the females. I have two pens of nice selected birds to breed from this season.—R. C. C., Missouri.

Lamp-chimneys with my name on them live to a ripe old age unless an unusual accident happens to them. They never break from heat.

They give the best light, too, because they fit and are made of tough glass, clear as crystal.

Let me send you my Index to Lamp-Chimneys. It's free.

Address, MACBETH, Pittsburgh.

Oranges and Lemons

When the right varieties are properly grown and planted, are money makers. Our new booklet on Citrus Culture tells all about the standard sorts, planting, cultivation, irrigation and packing the crop. Over 100 illustrations and something like 50,000 words of text. The price is merely nominal, namely, 25 cents. May we have your name for a copy?

San Dimas Citrus Nurseries
R. M. Teague, Prop.

IT'S PENNY WISE.

Policy to set out a good tree, costing good money and then let the sun burn the bark or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Manufacturing Company, 2124 Willow St., Los Angeles.

Irrigation and Pumping

THE UNIRRIGATED STRIP.

HOW to wet all the soil of an old orchard by irrigation, is a problem that confronts citrus fruit growers, especially when the summer sun asserts his power.

The good results that come from thorough wetting are shown this season of 1907 by the rampant growth and abundant blossoming of the trees.

The rainfall of two seasons previous was good and awoke the dormancy of that part of the root system scarcely reached by the usual methods of irrigation, the part of more or less width that lies along the tree row.

The copious and frequent rains of the present season have caused the awakened rootlets to put forth their energies in gathering plant food material in unusual abundance. What may be the result in fruit cannot, of course, be foretold; but the beginnings are auspicious, and we may be called on to dispose of a crop too large for the best results to the grower.

How we of the arid regions do boast of the great advantages of irrigation, and of our skill in the art of applying water; but we have to acknowledge, sometimes, that the hand of Nature has greater skill than ours in the distribution of the life-giving element. With all her demonstrations for our enlightment, no artifice of ours can approach her method in thoroughness, The water that comes from the skies, unburdened with earthly matter, has power of penetration and solution that stream waters, filled with the salts of the soil, cannot have.

What man has done and can do with running water is indeed wonderful; such vigorous growth and marvelous blooming, resulting from Nature's application of water from above us, should set us to studying to improve our method of flowing water along the surface.

Flooding probably comes the nearest to rainfall in wetting all the ground; but the objections lie against it of compacting the soil, of requiring too large a volume of water and too much labor, and of injury to trunks of trees by contact.

The furrow method so universally employed, seems to me the method to be improved.

The plan of making with one horse, by a tool called the grape hoe," the first furrows next to the trees has advantages; by means of the single guide wheel, operating like the rudder of a boat, the share of the tool will make an incurving furrow between the trees in the row, as the horse passes along in a direct line; such furrows, made on each side, afford a passage for water which partially irrigates the space, sometimes twelve feet wide, in rows of old trees.

Long continued irrigation in ordinary furrows induces a spread of the water to a considerable extent, both on the surface and beneath it, but the dry strip of the tree line is rarely penetrated by the flow on either side in ordinary furrows, for the usual period. Hand work in ponding between the trees in the row, or a horse tool to effect the same result would be a good practice.

Those whose lands are so situated that they can irrigate in two ways at right angles to each other, in alternate periods, have a great advantage.

The plan of running a subsoiler across the usual line of irrigation opens a passage or seepage; this is not, however, generally used.

We may always have recourse to frequent and deep cultivation to retain what it is difficult to supply.

In the youth of the trees, roots were developed by furrow irrigation near the trunk and these roots have reached out to receive water from more distant furrows, but, as the spread of the tree tops has increased, a considerable width of soil space is not drawn upon in the time of greatest growth, and good rains have to be relied upon largely to make this space give up its wealth of nourishment.

In this condition is found room for further development of the art of irrigation.—Chas. R. Paine.

DIVERSION FROM STREAMS.

Diversion from perennial streams is the most common method of securing irrigation water, and it is available for either great or small undertakings wherever unappropriated water flows in sufficient amount. In the regions where irrigation is most widely practiced there may no longer be such supplies available, but in the newer parts of the humid regions, farms are so situated that stream water can be readily secured.

After assuring himself in the manner described that a near-by stream carries sufficient water for his purpose, the next step for the farmer is to determine whether the water can be brought to his land at a reasonable expense. This will depend principally upon the length of the ditch which must be constructed.

The simplest way to find out how long the ditch must be is to run a line having the necessary grade from the highest point of the land to be irrigated upstream till it strikes the stream. The grade on which the ditch should be built, and consequently upon which this preliminary line should be run, will depend upon the quantity of water to be carried and the nature of the soil over which the ditch will run. In general, the larger the ditch and the lighter the soil the smaller the fall which can be given to the ditch; and the shorter the ditch the smaller the fall. However, the grade should not be too light, for the ditch may have to be made larger to carry the desired supply of water. On the other hand, the grade cannot be very heavy or the strong current will wear away the ditch banks. Therefore the range of the grades which may be given to a ditch is limited. In ordinary soils a grade of 2 inches in 100 feet may be given to small ditches, and in clay soils as much as 3 to 5 inches in 100 feet may be given.

Should the line run in this way be too long, the stream below the point where the line strikes it should be examined to see if there is any place where the water can be raised by a dam high enough to flow into the proposed ditch. In case no such place is found, a water supply from that source must be abandoned. If this preliminary line shows that the water can be brought to the land by a reasonable expenditure of labor and money, the ditch line should be carefully located.

It may be that the place where the line strikes the stream is not a convenient place for diverting water. In such a case the head of the ditch may be moved upstream, and a drop put in to avoid too heavy grades, or the head may be moved downstream and the water raised to the ditch by a dam.

FUNGUS ON BLACKBERRIES.

Very many of the blackberry and raspberry vines of the upper country are suffering from a severe attack of fungus disease known as Anthracnose. As the berry industry in many sections is a very important branch of fruit growing, a disease of this nature, when very prevalent, becomes a serious matter. Anthracnose is a fungus disease which makes its appearance early in the spring and is indicated by small reddish-purple spots on the canes and leaves, these spots merge into each other until whole patches are involved, and the disease girdles and kills the canes. Like all other fungus troubles, it is at its worst in the early spring when the moist conditions of the atmosphere and the tender condition of the host plants are especially favorable for its growth and spread. The best remedy for the disease is the removal of the old canes, which should be burned, and the application of a diluted Bordeaux, say bluestone, two pounds; lime, two pounds and thirty gallons of water. Of course, after pruning, all the wood cut out should be burned.

One of the old landmarks of Placerville, a venerable walnut tree, was blown down during the late storm. The tree measured 9 feet 4 inches in circumference, while two of its branches had each attained 24 inches in circumference.

Mica Axle Grease

lengthens the life of the wagon—saves horse-power, time and temper. Best lubricant in the world—contains powdered mica which forms a smooth, hard coating on axle, and reduces friction.

If you want your outfit to *last* and earn money while it lasts—grease the axles with Mica Axle Grease.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Probably Indigestion.

I have taken the Cultivator for 3 or 4 years, could not do without it, and now I want to ask you to please tell me what to do for my little turkeys; some of them are 3 weeks old and some a week old; they eat all right for a few days, then in the morning their wings drop down and they won't eat and their eyes shut as they are walking round. The droppings are all right now; I can't find any lice on them any place. If you can tell what to do I will be very glad; the eggs are hatched by turkey hen; she still has them; they have onions, green barley, curd, chick food and clear water.—Mrs. W. F. R., Chino.

I am sorry about your little turkeys. It is either indigestion or they are taking cold. I think it is really the chick feed. There is cracked corn in the chick feed and that is very bad for little turkeys. In one of Mrs. Chas. Jones articles on feeding young turkeys she says, "the least little bit of corn makes them sick and they die."

Over and over again I have warned our readers not to give the little turkeys any corn at all until they have "sported the red." This is not until their heads and neck become red like adult turkeys. Still people will persist in feeding chick feed, or cracked corn or corn meal, and invariably have trouble. If they must have grain give them cracked wheat or rolled breakfast oats, these do not turn sour or ferment in their stomachs, but corn does. Possibly yours may be taking cold from sleeping in a draught or from running in damp grass early in the morning, but I think it is the corn in the chick feed.—Mrs. A. B.

Little Turkeys.

In one of your articles you say: "Do not give the little turekys corn of any kind until they have sported the red?" What do you mean by that, and how can I know when that time arrives?—A. B. C., Downey.

When turkeys get to be about three months old the down on their heads and necks is replaced by corrugations of flesh (comb and wattles); these as they grow older become red and it is called "sporting the red." When they have become red they are matured enough to be able to eat corn without it injuring them; if they eat it too early it always ferments inside them and that is one of the worst things that can happen to either chickens or turkeys. The digestive organs of chickens are hardier than those of turkeys and they can stand more abuse. In the wild state little turkeys live only on insects and tender greens, they have to wait till fall for the seeds and grains, and by following nature in this you will raise every turkey.

Of course you cannot dig worms, grubs, and hunt grasshoppers enough to feed your turkeys; you must replace these with curd, hard boiled eggs etc., onions chopped finely and tender greens. Give them range and let them sleep in an open shed so they will have plenty of fresh air.—Mrs. A. B.

Inoculation.

After planting inoculated garden peas will it be necessary to inoculate clover or beans or does the same inoculation do for all plants?—C. D., San Bernardino.

If you want immediate effect, you had better inoculate when you change the variety of legume. It is known that the bacteria will either adapt itself to entirely new varieties or something else happens. It, however, takes time with most new varieties.—J. W. M.

Lippia for Tennis Courts.

A subscriber is anxious to know how much of a success Lippia repens is on tennis or other courts and would like to hear from those who have put the plant to such use. Will somebody enlighten us?

Toulouse Geese.

Can you inform me as to where I can get Toulouse geese eggs, and the price? Thanking you for the information.—Mrs. F. G. F.

FISH AND GAME LAWS.

At the recent session of the legislature a new law was passed placing a license upon the pastime of hunting. The law has received the approval of the Governor and goes into effect July 1st. After that date one who desires to sally out in pursuit of wild birds and game during the open season must procure a license.

The gist of the new game and fish laws of the state is given as follows:

Hunting license—For resident citizens, $1; for non-resident citizens, $10; for aliens, $25.

Open Season for Game.

Duck, October 1st to February 15th.
Quail, October 15th to February 15th.
Snipe, October 15th to April 1st.
Mountain quail, September 1st to February 15th.
Grouse and sage hen closed for two years.
Doves July 15th to October 15th.
Tree squirrel, September 1st to January 1st.
Deer, July 15th to October 1st.
Trout, May 1st to November 15th.
Golden trout closed for two years.
Black bass, June 1st to January 1st.
Salmon, in tide water, October 23d to September 17th.

Bag Limits.

Ducks, 35.
Quail, dove, curlew, ibis, plover, rail, 25.
Trout 50 pounds or 25 fish, none less than 5 inches in length.
Black bass, 50.
Tree squirrel, 12 in one season.
Deer, 2 in one season.

LITTLE BROWN MEN.

"Fruit growers of Sutter county have found it necessary to organize to protect themselves against the exactions of Japanese laborers. The Japs having driven out the whites from that section, have become so dictatorial that the fruit growers have been placed almost at their mercy and have been compelled to organize for protection."—Oakland Enquirer.

"A big crop is almost certain this year—bigger than for several years. Everybody knows there is not anywhere near help enough in sight to harvest it, and the Japs are getting so independent that they hardly want to work for a white man. What are we going to do about it?"—Winter Express.

Is this not characteristic of the Japanese? And is it not worth considering by all who look beyond the immediate present?—Lindsay Gazette.

It certainly is. The editor of the Sun had ample chance to witness the results of Jap labor in the beet fields at Oxnard, where they have gradually crept in until today they practically control the labor market, and a more tyrannical and exacting set of people never lived. Beside this, they have been found so tricky and unreliable that in doing business with them farmers and merchants are forced to watch them continually.—Exeter Sun.

"Gross ignorance is 144 times as bad as just ordinary ignorance."

OIDIUM OR POWDERY MILDEW

Continued from First Page

Summer Form of the Fungus.

The mycelial threads of the Uncinula spiralis are extremely fine—not over two ten-thousandths of an inch in diameter. They elongate and grow over the surface to which they are attached by their haustoria and at intervals send out upright branches—hyphae—thirty to forty ten thousandths of an inch long.

These hyphae are somewhat thicker than the mycelial threads, gradually increasing in diameter from the bottom to the top until they become two or three times as thick as the threads from which they arise. Cross partitions divide the hyphae into several cells, the uppermost of which finally becomes detached and forms a conidium or summer spore. The hyphae continues to grow and the second cell develops into another conidium. This process continues as long as the conditions are favorable throughout the summer, each hypha producing a large number of conidia. These conidia are egg-shaped and measure about 5x12 ten-thousandths of an inch.

When a conidium falls on a suitable part of the vine it sends out a germinating tube which fixes itself by haustoria and grows into a new mycelium which in turn produces more summer spores.

In this way, all the green parts of a whole vine may finally be covered with a coating of mycellium, hyphae and conidia, which together form the whitish or grayish matter we know as "Mildew" or Oidium.

Winter or Resting Forms.

In the autumn another form of the fungus is often produced. Among the felted threads of the mycelium may be seen with the unaided eye numerous round black bodies, which are perithecia, or receptacles containing the spores. These bodies have an average diameter of about 1-250 of an inch, which is about one-third the diameter of the dot of an i in the print of this bulletin.

Under the microscope they are seen to vary in color from yellow when unripe to nearly black when mature.

A mature perithecium consists of a nearly spherical case containing from four to eight cell-sacks called asci. The walls of this case are strong and resistant to cold and other unfavorable conditions which destroy the summer forms of the fungus. They are made up of thick polygonal cells and form a very efficient protection to the asci. An ascus contains from four to six spores.

Each perithecium is furnished with 10 to 25 hair-like appendages of about the same thickness as the mycelial threads and from one one-hundredths to one-fiftieth of an inch in length. These appendages are divided by several cross partitions and are coiled at the free end. They consist usually of a single thread, but occasionally branch.

How it Sticks.

The perithecia remain upon the canes and leaves or in the soil until the return of warm weather in spring. As soon as the temperature becomes sufficiently high, the walls of the perithecia break open and allow the asci to emit their spores. These spores, when they reach a leaf or growing shoot, germinate in the same manner as the summer spores and give rise to a new generation of Oidium.

The perithecia do not all emit their spores at the same time owing to the different conditions of the places in which they have passed the winter. Some may even remain in the soil until the following spring. Perithecia have been shown to contain spores capable of germination eighteen months after their formation. It is therefore impossible to completely exterminate the fungus in a vineyard in one year, however thorough the treatment. Burying the perithecia by plowing-in simply aids in their preservation and they are ready to cause a new infection two years later when brought to the surface again by later plowing. Although the Oidium was introduced into Europe as early as 1845, it was not until 1892 that the winter form of the fungus was found there. It was for this reason uncertain until that time that our Oidium and that of Europe were identical.

It seems probable that the fungus, under some conditions, can pass the winter in the conidial or summer form. At all events, in certain districts the perithecia have never been found and are therefore absent or very rare. They are very rare in the interior valleys of California. On the other hand, they are produced in immense numbers on vines within the influence of the summer ocean fogs. At Berkeley it is common to find thousands of them on every leaf and cane of a vine. More than 100,000 perithecia have been counted on the upper surface of a single leaf, and as each perithecium contains fifty or more spores, the number produced on a single vine may be hundreds of millions.

In Europe they are formed in September and October. In Berkeley they are found in abundance as early as the middle of June. Their formation seems to depend on weather conditions. If after a period of warm, moist weather, which has produced an abundant growth of mycelium, the temperature suddenly falls to near the lowest limit for the growth of the fungus (50 degrees F.), they are produced rapidly and in great numbers. These are weather conditions which often occur at Berkeley and in the valleys nearest the coast.

In the interior very different conditions exist. The fungus may grow abundantly during the spring and early summer, but there is seldom any fall of temperature at this season sufficient to cause the production of the winter spores. As the summer advances, the air becomes too hot and dry for the fungus, so that by the time the cooler weather of October arrives, most of the Oidium has disappeared and the abundant growth of strong mycelium which is necessary does not exist.

DIDN'T WANT THE COMPLEXION.

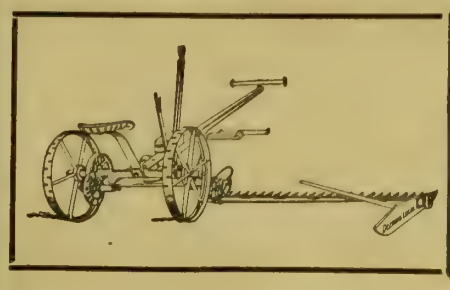
"Hab yo' got any medicine dat will purify de blood?"

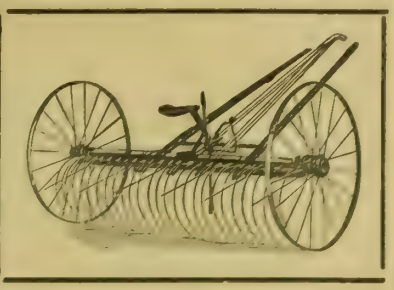
"Yes; we keep this sarsaparilla at one dollar a bottle. It purifies the blood and clears the complexion."

"Well, boss, hasn't yo' got suffin' fo' about fifty cents, jess fo' de blood? I don't keer about de complexion."

"'Tis true," said he, "I need a bill collector,
But I'm sorry that you cannot be the one."
He said it really pained him to reject her,
But then, "a woman's work is never dun."

The farmer's mint—the dairy cow.





Implements for the Ranch

THE BRAVEST BATTLE.

The bravest battle that ever was fought,
Shall I tell where and when?
On the maps of the world you will find it not;
'Twas fought by the mothers of men.

No marshalling troops, no bivouac song,
No banner to gleam and wave;
But, oh, these battles, they last so long.
From babyhood to the grave.

Yet faithful still as a bridge of stars
She fights in her walled-up town—
Fights on and in the endless wars,
Then silent, unseen—goes down

Oh, ye with banners and battle shot,
And soldiers to shout and praise,
I tell you the kingliest victories fought
Were fought in these silent ways.

O, spotless woman in a world of shame!
...th a splendid and silent scorn,
Go back to God as white as you came
The kingliest warrior born!

IMPROVEMENT OF HUSBANDS.

THERE are almost as many kinds of husbands as there are marriages. The good class needs no public praise. The opposite is made up of many kinds. There is the wife beater, for example.

Last month we met three women who bore stricking evidences, if we may use the term, of being married to a member of this species. One had two deep sores in her head, another had a dislocated wrist, while the face of the third was disfigured by black and blue spots of no mean dimensions. The latter explained that her peculiar coloring was due to the fact that she had refused to go out at eleven o'clock at night to purchase cigarettes for her lord and master.

In these instances, as well as where the husband drinks, uses abusive language, or neglects to provide properly for his family, the wife can seek redress at the hands of the law, and hundreds of these brutal life-partners have been cowed into a most pathetic submission when brought before tribunals of justice.

But what of the woman who suffers from a refined cruelty that no law in the land can remedy—not even the divorce court?

What of the man who deliberately tries to humiliate his wife before company? Not long ago we were one of three guests at a dinner party given by an old school mate. The hostess was a dainty little woman whose manners were irreproachable. The husband was known as a good sort. He had an excellent position and belonged to one of the best families in town. Yet, from the soup to the coffee, he lost no opportunity to embarrass and mortify his wife.

Instead of crackers the hostess had toasted bread sticks with the soup. These were greeted by the following remark: "Why don't you stick to crackers? Suppose you think this dry bread is more fashionable." The hostess smiled condoningly, and rang the bell for crackers. Then when the maid brought in the most appetizing roast, and set it before the master of the house, and instead of carving, he exclaimed angrily: "Why didn't you have this cut up in the kitchen as you usually do? You know I hate to carve." With this he jabbed his knife into the roast, cutting it down through the center and served it in chunks.

The little wife swallowed hard to keep back the tears, while the guests felt like leaving the table. However, the end was not yet. When the salad, which looked fit for a king, was brought in, the host brutally asked why she served such "mixed up messes." As far as he was concerned, he preferred substantial food, and without waiting for the maid, he got up and took his own plate to the kitchen, bringing it back with a generous helping of meat and potatoes. While he was absent the wife made a brave attempt to look unconcerned and take the matter as a joke, but met with little success.

At the close of the meal, we all felt like taking our host out in the backyard and thrashing him individually and collectively. However, we were his guests and could not show our disapproval; as for the wife we learned afterwards that she collapsed completely after our departure. She cried for hours, declaring that never again would she try to entertain when her husband was at home.

The casual observer may see traces of comedy in these incidents, but they are real tragedies to the wives concerned.

The modern Othello who shows signs of jealousy because his wife happens to glance at a full moon, or shake hands with the minister, or ask the hired man if the chores are done, is another genus that makes the marriage tie irksome at times.

And what of the man who holds the purse strings so tight that the wife had rather go in rags than ask her lord and master for financial assistance? He never actually neglects his family. He is too clever for that. But can one imagine a more humiliating ordeal for an independent woman than that of humbly begging her husband for every cent she uses for herself or the children, and to be compelled to account in detail to the bread-winner just how these nickels and dimes are spent?—Mrs. H. L. Farmer.

SAVING IN MILLINERY.

The girl who understands how to clean up and refashion her hats, often appears as well dressed as those who spend a lot of money on their millinery, and any good straw hat can be brought up-to-date by changing the color or by altering the shape or style of trimming. It is easy to lower a high crown by removing several rows of braid, or to give height to a low one by adding several rows, and the brims can be made any desired width by adding rows of fancy braid. A white straw hat that is only slightly soiled may be cleaned by rubbing with moist corn meal, and if very much soiled it may be cleaned beautifully by brushing with a paste made of lemon juice and flowers of sulphur. Apply vigorously to the hat with a small brush, and let the paste remain on the straw until it has become thoroughly dry, then brush it off with a clean, dry brush. If you are tired of the white hat, you can dip it in a strong solution of diamond dye for cotton of the shade wanted, and press it into the desired shape while the straw is still wet, and a faded straw hat can be made the color it was when new by dissolving some of the same dye for wool in alcohol and applying to the hat with a soft brush, and when perfectly dry it must be given a coat of thin varnish. Boy's hats may be brightened in the same way and will only need a new band and lining to make them as good as new. If you have roses or other artificial flowers that can be used again, the addition of new leaves which can be purchased for a trifle will give the flowers a fresher appearance, and by using old straw shapes and trimming, it is possible sometimes to have a stylish and becoming hat without any present outlay of money.—A. M. H.

CLEANING GLASS.

A small paint brush with long, strong, supple bristles is the best thing with which to keep cut glass free of dust. It is the only means of reaching the dust which only lodges in the small carvings. To wash cut glass use borax in the water, and the result will be a sparkling, shining receptacle that will glisten as brilliantly as it did when new. If a cruet bottle has become stained with vinegar sediment, or a vase with sediment from flowers, or any other piece of glass which it is hard to reach into to wash, chop up a raw potato (peeled) and put it into the bottle with sufficient water or suds to just cover the potato; leave it for several hours, giving an occasional shaking; empty and rinse well; if necessary, repeat. Results will be pleasing.

CHARGE OF THE MAD BRIGADE.

(With acknowledgements to Tennyson)
Half a block, half a block,
Half a block onward,
Packed into trolley cars
Rode the six hundred.
Maidens and matrons hale,
Tall spinisters, slim and pale,
On to the Bargain Sale,
Rode the six hundred.

Autos to right of them,
Hansoms to left of them,
Flying trains over them,
Rattled and thundered.
Forward, through all the roar,
On, through the crowd they bore,
To Price and Sellers' store
Rode the six hundred.

When at that mart of trade,
Stern-faced and unafraid,
Oh, the wild charge they made!
All the clerks wondered.
Their's not to make reply,
Their's not to reason why.
Their's but to pacify
All the six hundred.

On bargains still intent,
Homeward the buyers went,
With cash and patience spent,
And friendships sundered.
What tho' their gowns show rents—
They have saved thirty cents;
Noble six hundred!
—Louise Stevens in the Woman's Home Companion.

THE SPOILER.

A woman there was and she wrote for the press
(As you or I might do),
She told how to cut and fit a dress,
And how to stew many a savory mess,
But she never had done it herself, I guess—
(Which none of her readers knew).

Oh, the hour we spent and the flour we spent,
And the sugar we wasted like sand,
At the hest of a woman who never had cooked
And now we know that she never could cook)
And did not understand.

A woman there was and she wrote right fair
(As you or I might do),
How out of a barrel to make a chair,
To be covered with chintz and stuffed with hair,
Twould adorn any parlor and give it an air!
(And we thought the tale was true).

Oh, the days we worked and the ways we worked
To hammer and saw and hack,
In making a chair in which no one could sit,
A chair in which no one could possibly sit
Without a crick in his back.

A woman there was and she had her fun
(Better than you or I);
She wrote recipes and she never tried one.
She wrote about children—of course, she had none;
She told us to do what she never had done
(And never intended to try).

And it isn't to toil and it isn't to spoil
That brims the cup of disgrace;
It's to follow a woman who didn't know beans
(A woman who never had cooked any beans),
But wrote and was paid to fill space.
—The Congregationalist.

SEMITROPIC FRUITS FOR HOME GARDEN.

Fruits for the home garden is always an attractive subject, because it comes so close to home. All of us know of some good varieties of fruits that thrive in the temperate zones, but when it comes to selecting the tropical and semitropical fruits, it is quite new to most of us.

The commercial varieties of fruits of this class are quite common to all of us. There are, however, many choice varieties that are not common and are desirable for the garden.

In addition to the Washington navel and Valencia orange, St. Michael and King are very desirable. They both come late and in localities where Valencia loses its fine quality in midsummer as it does in the interior, these varieties are very delicious.

King takes the place of Tangerines that come early in the season. It is of fine quality, but should not be planted in places exposed to severe north winds as it is very sensitive to them.

Villa Franca lemon is perhaps the best for the garden situated in the interior; for coast regions, Lisbon is considered the best.

The Pomelo is a popular fruit and should be in every home orchard. Marsh's Seedless is a choice variety, being practically seedless and consequently easy to prepare for the table. There are a number of varieties of Pomelos on the market, and they are all good as far as flavor is concerned. There is very little difference in this respect. The average Pomelo has from twenty to sixty seeds, and they occupy considerable space. Those of large size and few seeds soon impress us with their superiority, and it is well to bear this in mind when planting.

The Advance loquat is a desirable fruit and is useful in many ways. Other varieties of loquats are also desirable. Some of the smaller varieties are, to our mind, the best flavored, though there is very little edible substance to them.

The pomegranite is one of our most delicious fruits and is almost wholly free from the attacks of insects and disease.

Next to the orange, the fig is perhaps the most popular semitropic fruit in California. There are numerous varieties that are adapted to various sections of the country and only trial can determine which is best for any particular section. For a black fig, the old Mission is excellent. For regions near the coast, few figs will mature properly. Where the climate is right, Calimyrna is by far the superior of any other variety. This, however, cannot be successfully grown without the Capri fig.

The olive comes in for a place in the home garden, and where the climatic conditions are right it is exceedingly ornamental, especially when large.

The variety that gives the best satisfaction for general use is Mission. There are several types of this olive, the large one being the best. It sells on the market where it is grown when other varieties are a drug. It makes a good pickle, and good oil. It is perhaps not as desirable in cold locations as Columella or Santa Catarina, which ripen early, thus being out of the way before severe freezes come.

The largest olive is Sevaliano and Ascolano is next. They are used for pickling green, making the Queen olive that is imported.

While olives, and the Mission in particular, will bear good crops alone, still it is known that two varieties planted together give best results. Santa Catarina and Mission are well adapted for such planting. The characteristics of the Mission are the best determined in California because it is more widely planted.

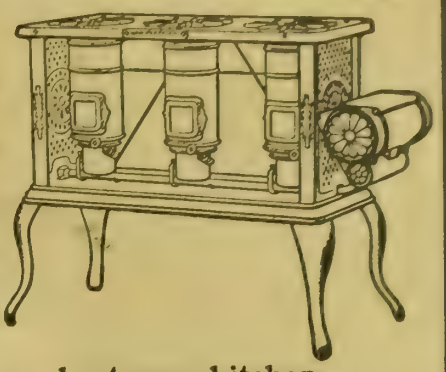
PROFESSIONAL ADVICE.

"It wouldn't do yer a bit of good, jedge, for me to 'splain how I cotched dem chickens, for yer couldn't do it yerself if yer tried it forty times, and yer might get yer hide full of buckshot. De best way for yer to do, jedge, is for yer to buy yer chickens in de market like udder folks do, and w'en yer wants ter commit any rascality, do it on de Bench, whar yer am at home!"

The Junior Monarch Hay Press Co. of San Leandro are advertising their Junior Monarch Hay Press and Little Giant Hay press in the Cultivator at the present time. Those who have used this firm's production are loud in praises of the same, and those who may want anything in the line of goods put out by this firm, can rely upon receiving a first-class press. Over 16,000 of these presses are now in use. So far, the claim is made that never a one has been returned. Send for their catalogue No. 21, and see what some of their many customers say of their goods. Their office and factory is at San Leandro, Alameda Co., California.

George F. Wilder, a prominent poultry dealer of Petaluma, is about to establish an extensive chicken ranch on the Holburn tract, between San Jose and Campbell.

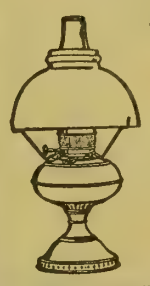
Use A
NEW PERFECTION
Wick Blue Flame Oil Cook-Stove



Because it's clean.
Because it's economical.
Because it saves time.
Because it gives best cooking results.
Because its flame can be regulated instantly.
Because it will not overheat your kitchen.
Because it is better than the coal or wood stove.
Because it is the *perfected* oil stove.

For other reasons see stove at your dealer's, or write our nearest agency.

Made in three sizes and fully warranted.



The Rayo Lamp cannot be equaled for its bright and steady light, simple construction and absolute safety. Equipped with latest improved burner. Made of brass throughout and beautifully nickeled. An ornament to any room, whether library, dining-room, parlor or bedroom. Every lamp warranted. Write to our nearest agency if not at your dealer's.

Nothing but the very finest. Several fine cockerels, $5 each. Write for full description of them.

Harry McIntire, San Diego, Cal.

Runt-Homer, and Hen Pigeons

THE FARMER.

The farmer has the most sane and natural occupation and ought to find life sweeter, if less highly seasoned, than any other. He alone, strictly speaking, has a home. How can a man thrive and take root without land? He writes his history upon his field. How many ties, how many resources, he has—his friendship with his cattle, his team, his dog, his trees, the satisfaction in his growing crops, in his improved fields; his intimacy with nature, with bird and beast, and with the quickening elemental forces; his cooperation with the cloud, the sun, the seasons, heat, wind, rain, frost; nothing will take the various distempers which the city and artificial life breed out of a man like farming, like direct and loving contact with the soil. It draws out the poison. It humbles him, teaches him patience and reverence, and restores the proper tone of his system.

Blessed is he whose youth was passed upon a farm. Cling to the farm, make much of it, put yourself into it, bestow your heart and your brain upon it, so that it shall savor of you and radiate your virtue after your day's work is done.—Oakley Eagle.

The Produce Markets

Los Angeles Markets

LOS ANGELES, April 24, 1907.

Butter.

Butter arrivals totaled nearly 60,000 pounds yesterday most of which came by steamer from the north. About half this amount went directly into cold storage and will in no way affect the official selling price.

Valley Creamery	47½
Coast fy,	40
Cooking	20

Cheese

The receipts of cheese yesterday, both local, northern and eastern, was unusually heavy. No price changes were recorded as a result of the big receipts, though it may tend to weaken the market tomorrow.

Cal. Young American, per lb.	21
California Anchor	20
Cal 3-lb. hand	21
Northern, fresh	19
Domestic Swiss	22
Imported Swiss	30

Eggs and Poultry

Eggs continue steady at unchanged prices. Receipts yesterday amounted to more than the estimated amount needed to meet consumption, but this is an exception to the average arrivals for several days past and the market has been firm.

Eggs local, per doz	21
Northern Candled	19
Fresh Eastern	18

The following are average prices which dealers pay to producers for live weight:

Hens, per lb.	16
Young Roosters, per lb	18
Fryers	22
Broilers, per lb.	24
Old Roosters	8
Turkeys	17
Geese	15@16
Ducks	15@16

Live Stock

The following quotations are f. o. b., Los Angeles, on all stock.

Hogs, 200 lbs.	7.75@8.00
Prime Steers.	5.50
Heifers	4½
Calves per lb.	5
Sheep, ewes, per head	5.00@5.25
Lambs per head	6.50
Wethers	5.50

Potatoes

The price of eastern potatoes weakened materially again today, several cars of Wisconsins selling wholesale at $1.50 per hundred. A few days ago Wisconsins sold at this figure, but since that time there have been none offered lower than $1.60 to $1.70, but at these figures there was little demand and none sold. The offerings this morning were readily accepted and dealers bought freely. This puts the selling price to the retail trade at about $1.70@1.80 per hundred.

Sweets, Yellow, per sack	5.00
Sweet, White per sack	4.75
Colorado	2.05
Minnesota	2.00
Early Rose, Northern	2.50
Early Rose, Eastern,	2.25
Oregon,	2.25

Vegetables

Green vegetables are not very abundant as was the case during the greater part of last week, and prices are generally a little higher as demand is still strong. Since the glut in bunch goods a few days ago, particularly turnips, the Japanese gardeners have been withholding from market this variety of vegetable for the purpose of forcing prices upward, which they have done successfully and hardly a bunch of turnips was obtainable at noon today at 35@40c a dozen bunches.

Asparagus, lb	10@14
Beets, per doz	40@60
Bell Peppers, Green, lb	5
Cabbage, sack	75@1.00
Chili Peppers, Green	30
Chili, Dried, per lb.	13½
Cucumbers, per doz.	75@1.50
Cauliflower, per crate	3.00
Carrots, per doz	35@40
Celery, per doz	30@50
Egg Plant, per lb	15
Garlic per lb	6
Green Onions, doz. bunches	25@30
Lettuce, per crate	40@75
New potatoes, per lb.	5@6
Lima Beans, per lb	7@8

Onion receipts were large today and prices declined on account of the increased supply. The bulk of these onions are now coming from Coachella. Prices to the retail trade went down about 10 cents per crate to $2.20.

Onions, Aust. Northern, sk	3.50
Nevada	3.20
Bermudas	2.20
Parsnips, per doz	35@50
Rhubarb, per lb.	3
Radishes, per doz	15@20
String Beans, per lb	8@12
Sugar peas, per lb	2@3
Tomatoes, Mexican crate	1.50@2.00
Turnips, doz. bunches	10@20
Wax Beans, per lb	16@18

Citrus Fruits

Lemons	2.00
Valencias	1.50@2.00
Navels	1.25@1.50
Grapefruit Seedless	2.00@2.50
Grapefruit seedlinggs	1.25@1.50

Fresh Fruits

Apples, Bellefluer, per box	1.50
Apples, Ben Davis	1.50

San Francisco Markets

SAN FRANCISCO, April 23, 1907.

The market was without any change whatever, either as to price or ton. Business was dull on the Street, and no sales were made on 'Change.

Butter.

One carload of oranges arrived, but the market was still largely supplied and weak. Strawberries went at about the preceeding day's price. The steamer Umatilla on Monday had for British Columbia 28,238 pounds of dried fruit, 11,050 pounds of raisins and 765 packages of fresh fruits.

SICILY LEMON SALES.

Twenty thousand boxes of Sicily lemons, steamer Irene, were sold today. There was a fractional decline on 360s, otherwise the market is practically unchanged. The bidding was fairly spirited.

Fancy 300s sold for $4.00 to $4.40; seconds, $3.60 to $4.05.

Fancy 360s sold for $4.15 to $4.40; seconds, $3.75 to $4.10.

The next sale will be Thursday, when 32,000 boxes will be offered.

NEW YORK, April 22.—The market is easier. Weather fine. Forty-one carloads of oranges and one of lemons sold.

CALIFORNIA CITRUS SHIPMENTS.

LOS ANGELES, April 23.—Oranges, 227; lemons, 14;. Total to date this season, 15,657 cars, of which 1517 cars were lemons. Total to same date last season, 17,374 cars, of which 1727 were lemons.

EGGS TOO SLOW.

The hens of Kansas and Oklahoma produce 12,000,000 eggs a month for the shippers to handle, besides the eggs consumed in the homes of the state and territory.

This means the shippers send out more than one hundred cars of eggs a month, and the Oklahoma and Kansas Egg Shippers' Association held a meeting at the Midland hotel yesterday afternoon to take some steps to obtain better car service.

The members of the association say the car shortage in Kansas and Oklahoma is now so distressing that large quantities of eggs will spoil before they can be marketed if some relief is not given.

Representatives of the Union Pacific Missouri Pacific, Atchison, Topeka & Santa Fé and the St. Louis & San Francisco railroads attended the meeting and it was made plain that little relief is in sight for the egg shippers. However, it was agreed that every effort will be made to send "return cases" into Kansas and Oklahoma at once. Not only does a car shortage exist, but a shortage of egg cases as well.

The shippers send out eggs packed in cases that are supposed to be returned to them. The railroads are slow in accepting "return cases" for snipment and that works a hardship on the egg shippers. It was agreed to send telegrams to the railroads, naming the localities where cases and cars are worst needed, and depend on the tender mercies of the railroads for relief.

"If the railroads refuse to ship us the boxes or to furnish us cars we're simply helpless," John Stewart of Concordia, Kas., president of the association, said. "We will join in an appeal for relief and we must have it. The egg season is on early in Kansas and Oklahoma. March will probably be our largest month this year. The railroads now promise to furnish us cars where they are most needed. And they're needed in every city and town."—Witchita Eagle.

Poultry Fillers.

WRIGHT'S GREEN MEADOW DAIRY.

The Reed & Bennett auction sale near Watts, on the 17th, was one of the largest and most successful sales ever held in Southern California. The dairy herd sold comprised about 300 cows and heifers, and was probably one of the finest dairy herds in this portion of the state. Messrs. Briggs & Weber opened the sale promptly at the hour, and sold them off at the rate of about one a minute. The prices ranged from $40 to $115, and totaled nearly $2000 more than the owners had estimated, which shows the good demand for dairy cows. The old time Spanish barbecue conducted by Mr. Remerex, was highly appreciated by all. Mr. Wright, the former owner of the dairy, was highly pleased not only with the successful termination of a life long career as a dairyman, but with the happy spirit with which Mr. Briggs held the crowd during the long and trying sale.

It is a mistake to keep the brood sows thin in flesh. They should now be in good condition and should be kept gaining till breeding time, which is not far in advance of this time. The brood sow has a heavy task ahead of her and the more of vitality she has in store the better she is able to do by the next litter. It is hardly right to expect breeding animals to "make bricks without straw."

"Bigga police say, 'Mova on! Move on_ when I sella the banan on the corner, but he say, 'How do! Fine day!' to saloona man who sell all night."

"Mary, is that Mr. Brown downstairs? I thought I heard him just now."

"No'm," Mary answered; "that wuz the dawg what wuz growlin."

Confident that a trial will prove the superior merits of

West Coast Stock Food

Beyond question the best condition powder made.
We will send to new customers one 25-lb.

$3.00 Pail for $2.00

or one 50-lb. $5.75 double sack for $3.50, and will prepay the freight to any point west of the Rockies. Not more than 50 lbs. to each one, and we reserve the right to withdraw this offer without notice when we have received all the orders we care to fill at these very low prices.

We are presenting no cheap premiums nor offering any gaudily colored pictures, but we are making this strictly legitimate business offer for the purpose of inducing more to try it. We thus hope to add to our large number of steady customers. We are charging up the difference and the freight to our advertising account, feeling sure that a trial of the goods is the very best advertising.

There are no strings to this offer. Just send us your name, your postoffice address, the freight station to which you want the goods shipped, mention this paper, and we will do the rest. Send money order or check with your order, and if everything is not exactly as represented your money will be refunded. The First National Bank of this city, or Bradstreet's Agency, or any leading firm, can inform you as to our reliability. WEST COAST STOCK FOOD has for many years been a standard condition powder in this section. See our full page adv. in the March 7th and 28th issues of this paper, or send for circular with testimonials.

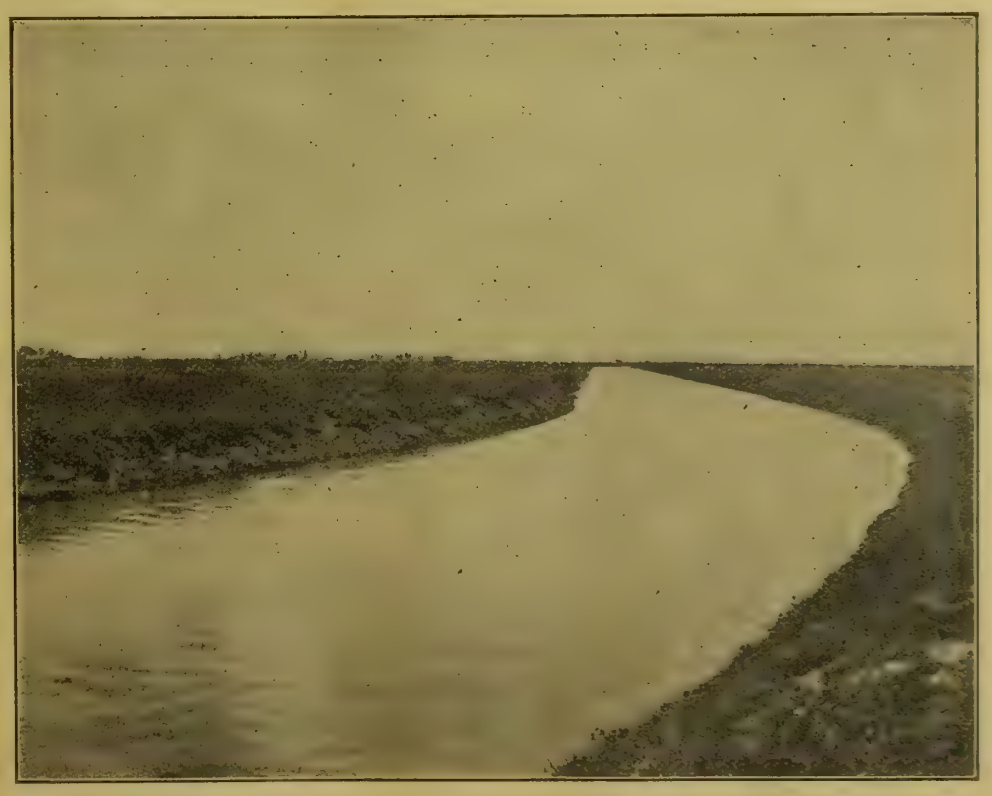
Scenes in Sunny Stanislaus County

Oranges



One of the Lateral Irrigation Canals

STANISLAUS County claims the proud distinction of being "The Gateway County of the Great San Joaquin Valley," and to which she is justly entitled.

Her splendid irrigation works are not owned by private capital, as is the case with so many irrigating systems in California, but by municipal corporations, created under a State law known as the Irrigation District Law.

Under the provisions of this law the limitations of an area called "District" are defined, and the electors within that district vote upon the proposition of issuing bonds based upon the land within such district, the moneys so raised to be employed in putting in the irrigation system.

Under this arrangement the land owns the water. There are no such things as water rights in these districts, so that the land cannot be deprived of it as is the case in so many districts where "paper rights" allow a man to carry, figuratively speaking, his water in his pocket.

Pickling Ripe California Olives

Synopsis of a Bulletin Issued by the College of Agriculture, University of California

By FREDERIC T. BIOLETTI, University of California

THE increasing favor with which California pickled olives are received throughout the United States, and the consequent increase in demand, result in the receipt of a large number of letters by the Agricultural Experiment Station requesting information regarding methods of pickling. While no new experimentation has been undertaken in this matter by the Station since the appearance of the last bulletin on the subject, the demand for information makes it desirable to publish a summary on the results obtained, as the editions of former bulletins are exhausted.

While undoubtedly improvements have been made during the last five years in the methods of pickling, more especially in the mechanical details, the essentials of the methods remain the same.

Nutritive Value of Olives.

Pickled ripe olives constitute an extremely nutritious and digestable form of food. They contain a large amount of oil, carbohydrates and some nitrogenous matter, and in some countries replace meat to a certain extent. Pickled green olives, such as those imported from Spain are, on the contrary, indigestable and contain much less nutriment. They are made from unripe fruit and are, therefore, as far as their use as food is concerned, in no way superior to unripe apples or peaches. They are simply a relish and to be used in very limited quantities in the same way as pickled walnuts and cucumbers. A meal of bread and ripe olives, on the other hand, is not only palatable, but nutritions and sustaining, and the amount eaten is to be limited only by the same considerations as that of any other good, wholesome food.

The Queen olives were the best of their kind to be found on the market, and when compared with the first two samples of ripe pickles, which are typical of good ripe Missions, show just one half the amount of nutritive material. This does not show the whole difference, for there is no doubt that the nutriment in the ripe fruit is in a much more readily assimilable form than in the green. The thir sample was grown on an over-irrigated soil, and while inferior to the first two, is much superior to the green fruit in both quantity and quality of nutriment.

Gathering the Olives.

Whether olives are to be used for pickling or oil-making, it is very important that they should be picked carefully and at the right time. For green pickles they should be picked very soon after they obtain full size, but before they have begun to color or soften.

For ripe pickles they should be gathered at the same stage of ripeness as for oil-making; that is, when they contain the maximum amount of oil. This is soon after they are well-colored, but before they have attained the deep black which signifies over-ripeness. If the olives are gathered too green the oil will be bitter; if too ripe, it will be rancid. On account of the different degrees of color in different varieties of olives, it is difficult to tell from their appearance when they should be gathered. When they can easily be shaken from the tree they are ripe enough. If they commence to fall without vigorous shaking they are over-ripe. For whatever purpose the olives are to be used they should be carefully gathered by hand. Rakes or sticks should never be used, as they bruise the fruit and break off great number of fruit-shoots needed for the following year. It is well to sort the olives as they are being picked, separating out the bruised, diseased or over-ripe fruit.

Grading and Sorting.

It is extremely important that all the olives in each lot of pickles should be as nearly as possible uniform in character, in order to facilitate the process of pickling and to produce an attractive appearance. Olives of different varieties, and even those of the same variety from dissimiliar locations, should never be mixed. The first sorting is done while gathering, and the under-ripe, over-ripe and injured fruit is then graded according to size by means of a mechanical grader. In this way the olives are separated into different lots, which will each contain fruit on which the different processes of pickling will act uniformly. A grader adapted to handling soft fruit that will not bruise the olives, must be used. After the pickling process is finished there will be a distinct difference of color between different olives of the same lot. Another sorting according to color is then advisable. This must be done by hand, and either two or three colors may be separated—dark and light or black, medium and greenish, according to the variety.

Unfortunately the consumer has acquired a taste for jet black olives and will accept a lighter olive only at a lower price. This has led to more or less questionable practices which have for their object the retaining of the natural dark color of some varieties, and the coloring of those which are naturally light in color. It is very seldom possible to put a perfectly black pickled olive on the market without the use of some dye or mordant, which, even if harmless, certainly does not improve the flavor or wholesomeness of the food. This practice would be unnecessary if the consumer could be taught that some of the best varieties of olives are naturaly light gray or brownish green in color after pickling, and that any black olive is to be suspected of treatment with substances that are unnecessary for the production of the best quality.

Pickling Ripe Olives.

The successful production of pickled olives is a matter of experience and depends almost altogether on the individual judgment and skill of the producer. No method can be given which is suitable to all cases, and the best method must be modified according to the nature of the olives to be treated. The following scheme, therefore, is to be considered as a mere outline, to be carefully adapted and modified by the operator at each stage of the process:

1. Place the olives in a solution, composed of two ounces of potash lye to one gallon of water, for four hours. Repeat this once, or twice, if necessary to sufficiently remove the tartness.
2. Rinse the olives thoroughly and replace the lye solution with fresh water. Change the water twice a day, until the potash has been removed from the olive, as judged by the taste.
3. Replace the water with brine composed of four ounces of salt to a gallon of water and allowed to stand two days.
4. Put in brine of six ounces of salt to a gallon of water for seven days.
5. Put in brine of ten ounces per gallon for two weeks.
6. Put finally into a brine containing fourteen ounces of salt to the gallon of water.

In order to make this process a success the following considerations should be kept in view:

1. Great care should be taken not to allow the the olives to come in contact with anything that will injure their flavor. The vats or other receptacles used for pickling should be perfectly clean, odorless and tasteless. Earthenware is the best material, but it is usually cheaper and more convenient to use wooden receptacles thoroughly treated with boiling water and soda until they are sterilized and all taste of the wood removed. Any wood (such as pine) with strong taste should not be used. The vats should be provided with a removable wooden grating, fastened one or two inches from the bottom, and a close-fitting, floating wooden cover to prevent access of air, which spots the fruit. On top of the vats should be placed a cover of thick cloth or of wood to exclude the light and dust. Each vat should be provided at the bottom with a wooden spigot for drawing off the solutions. The thickness of the layer of olives should not be more than two feet,

2. It is best to use good potash lye. Some of the brands of lye are so impure that it is impossible, without a chemical analysis, to tell within forty per cent how strong the lye solution actually is when made up. "Greenback lye" has been found the most reliable, and may be considered as one hunderd per cent. pure when making up the solution.

Impure lyes are often used with success, but it is necessary to use more of them. The principal adulterant is common salt, and if soft or over-ripe olives are being pickled this may be an advantage, as it keeps the fruit firm. If we have pure lye, however, we can add the salt if necessary and leave it out if we do not need it, As salt is much cheaper than lye it is better to buy it separately and not to pay the price of lye for it as we do when we buy impure grades.

The length of time which the olives should be left in the lye, and the number of times the lye should be renewed, can only be determined for each variety and each locality. The object is to extract the tartness of the olive, and at the same time to soften the skin sufficiently to allow the tart or bitter substance to be soaked out in the subsequent treatment with pure water. The tougher and thicker the skin of the olive, and the more intense the tartness, the longer must the lye treatment be continued. The lye is sometimes made twice as strong as recommended above, and the treatment correspondingly shorter, but the results are not so good. Just enough lye solution should be used to exactly cover the olives, and occasionally, during the soaking, some of the solution should be drawn off below and poured on top to insure an equal treatment of all the fruit.

3. Only the very purest water should be used, both for the lye solution and for the subsequent soaking. Canal and river water, or any water that contains a great deal of organic matter, should never be used, unless it is practicable to boil it first. Distilled water, such as can sometimes be obtained by condensing the waste steam from a boiler, is the best, on account of its purity and its greater extractive power, provided, of course, it be free from oily flavors. The length of time during which the soaking in pure water should be continued varies very much in accordance with the character of the fruit. If the olives are firm and show no signs of becoming soft it should be continued until the tartness is sufficiently extracted. This will vary usually between ten and twenty days. The moment that the olives begin to show signs of softening, however, they should be placed in weak brine, even though the tartness has not all disappeared. What remains can then be extracted by the brine, which should be changed two or three times, as may be necessary. It is not necessary to change the brine quite so often as the pure water, once in two days being generally sufficient.

If the olives are soft at first, before treatment with lye, or if they are of a kind that softens rapidly in the lye, it is necessary to use brine from the beginning either immediately after treatment with lye, or, in extreme cases, with the lye. This method suggested by Prof. Hilgard has been used with marked success. The lye solution in this case should be made by adding two ounces (or less, if the olives are not very bitter) of lye and four ounces of salt to each gallon of water. As the lye acts much more slowly when used in combination with salt, it may be allowed to stay on the olives for a longer time without injury—eight to twelve hours or even more. This lye and salt solution tends to harden and shrink the olives. The shrinkage, which occurs when brine is used from the beginning on naturally soft olives, is not a disadvantage if not carried too far, as such olives are generally too watery to be palatable or to keep well. They can, moreover, if shrunk too much, be made plump again by a

Deciduous Fruit Culture

By J. W. MILLS

SOIL, CLIMATE AND VARIETIES.

WHY is it that every year there is more or less digging up of one variety of fruit trees and planting out another? It appears to us that too much confidence has been placed in the climate and soil.

It is true that we pride ourselves on our superb climate. It is nice to live in, but it is not good for everything. Certain fruits require certain climatic conditions to produce at a profit that should be expected. While conditions may be conducive to proper growth, they may not be right for fruiting. The olive in most sections of Southern California demonstrates that.

Olives were planted by the wholesale in the south at one time. The trees thrived exceedingly well, bloomed abundantly, and some seasons produced good crops. Were the trees not exceptionally hardy and full of vitality, perhaps so many would not have been planted. Nearly everybody who thought that they had land that would raise olives planted a few, and many went into it extensively before it was definitely demonstrated that they would pay.

It turned out that the conditions which favored this aspect of the industry were not at all known. Incidentally, Northern California caught the boom. It was a weak boom as all of their booms are as compared with the lower end of the state, and it turned out that the olive was at home there as regards climate and soil.

In Southern California, it was demonstrated beyond a doubt that the Washington navel could be grown to a greater degree of perfection than any place else it had been tried. Had it acted as the olive did, no amount of cultural persuasion could have made our present area turn out nearly 20,000 carloads of navel oranges per year. We may say that Southern California has proved to be a perfect home of the navel, but this is too broad.

Two hours' ride, and perhaps less, will connect us with two localities, one of which is admirably adapted and the other much less so to the growth of a certain variety of orange. A variety of soils will produce equally as good oranges, but the climatic conditions are wrong in many instances. Florida found this to be the case with the Washington navels. Situations near the coast in Southern California produce Valencias that keep on the tree and sell better than those raised further inland.

At the Pomona Experiment Station there were from 150 to 200 varieties of plums, nearly all of which grew and blossomed well, but not more than twenty bore good crops. This continued for about ten years. When the trees were young, more bore fruit than when they reached maturity. All of these varieties of plums are desirable varieties in some parts of the country.

Another striking example was with the Persian grapes. These, with the exception of one or two never bore enough to make them worthy of record. When cuttings were sent in to Coachella valley some varieties that were absolutely barren at the station, bore immense crops. Some varieties bore continually through the growing season there while in their former place they showed no sign of such qualities.

Unprofitable planting will never be so extensive as formally for the reason that experience extends over a longer period of time. In plain English, we are learning among other things, to "go slow."

SPRAY EARLY.

If you have some Nonpareil almonds, the chances are that they will have shot-hole fungus or prune rust. The latter is the most destructive of the foliage of this variety.

In fact it attacks nearly all varieties of almonds, but the paper shells are particularly subject to it. Spraying with Bordeaux mixture will prevent the attack of this disease if it has not made its appearance or is not just entering the tissue of the leaves. A good microscope and some experience will be necessary to determine if the latter is the case.

Spraying late in winter where the land can be run over immediately after a rain will be the safest. Large plantations or trees on heavy land that is liable to be wet late in the season, should be sprayed early so that there will be no danger of the season going by without spraying. It must be remembered that the prune fungus will strip the entire foliage from the almond tree in a short time and that means a deterioration of the trees and the crop.

POOR PRUNING.

A few summers ago I saw an orchard that had been pruned with an axe the previous year. If anyone had done as poor a job trimming out my grove of despised second-growth post-oak, he would have had to quit as soon as I found out.

An axe is a poor tool with which to prune an orchard. I know of no better tools than a sharp saw and knife with a keen edge, the one for the large limbs, the other for small limbs and water sprouts.

Besides the usual removal of cross branches, those that are too low and water sprouts, there is this spring in many orchards the added work of taking off branches that were broken by the heavy crop of last year. Much care should be used in taking these off so as to leave a smooth surface close to the trunk or large branch where they are removed. A stub six inches or a foot long will never amount to much of anything as a bearer of fruit. It only disfigures the tree and induces disease and decay. Take off the broken limbs as you would any other that you want out of the way.

A good way to have a smooth cut where a large branch has to be removed is to cut it off a foot or more from where you wish, then cut off the stub that is left. In this way you run no risk of having the branch tear the bark down as it falls. It also often enables you to get closer to the tree or large limb with your saw than you could any other way.

The wounds made in removing branches an inch or more in diameter should be painted the day they are made.

We paint smaller wounds, as the spring winds check the wound so soon, and you never know the coming day's weather; therefore it is best not to "wait till tomorrow" before covering the wounds. White lead and oil make the ideal paint for this purpose. As we have but a few hundred trees, we buy the mixed paints that come in half-gallon cans. They are ready to use as soon as stirred thoroughly.

When burning the brush, it must be far enough from the trees to prevent the heat from injuring them.

FINE OLD APPLES.

I noticed an article in your paper of April 18th stating that there are thirty-five-year old apple trees at the Hicks ranch in San Bernardino county, California, that have a ditch of water running constantly within five feet of the trunks and yet are very thrifty and bear nearly every year apples of the highest quality.

The writer being a present owner of the property wishes to correct the article somewhat. The trees are twenty-six years old this spring; they are on a margin of a small stream of water constantly running at the root of the tree and since coming into bearing never have failed bearing a good crop, unless killed by frost. They now bear from a thousand to fifteen hundred pounds to the tree. There are fifteen of them in number. The varieties are of the White Winter Pearmain, Kentucky Red Streak and New Town Pippin.

The ranch is situated near the famous summer resort, Oak Glen, nestled in the foothills of "Old Grey Back," the elevation being about 5000 feet. It is also about sixteen miles from Redlands.—A. A. Warren.

TRANSPORTATION FACILITIES.

At a meeting of peach growers held in Atlanta the first steps were taken to secure better shipping facilities and more favorable freight rates on fruit products from that part of the country to the Eastern markets. Georgia growers claim that it costs more to ship their peaches to New York than is charged for hauling the same fruit from California to the same market. Freight rates on fruit are much higher than rates for hauling dressed meats, both classes requiring refrigeration.

At this meeting a transportation committee was appointed, and it was decided to assess members of the organization from 25 to 50 cents per thousand trees, to defray necessary expenses of suits, if legal action is necessary to secure an adjustment of freight rates. With something like 10,000,000 bearing peach trees in Georgia alone, this assessment should provide enough money to prosecute this work vigorously.

Another matter brought before this meeting was the service given by refrigerator car companies, and a resolution requiring them to place in each refrigerator car a recording thermometer was referred to the transportation committee. It is claimed that it frequently happens that, notwithstanding the cars are well iced when they leave the shipping station and are well supplied with ice when they reach their final destination, considerable fruit will be found to have spoiled, and this is undoubtedly due to the fact that somewhere in transit the cars were without ice. A recording thermometer would show the temperature at all times between the shipping station and the destination.

It is believed that the Southern railroads will make lower rates on fruits this season. Prospects for a peach crop are very fine, and from present indications the problem of distribution and transportation will be an important one.

SPECIAL CLEFT GRAFTING.

In grafting an apple seedling, it sometimes happens that the stock to be grafted is a little too small to work well in regular cleft grafting and at the same time too large for whip grafting. In this event a modification of side grafting can be successfully used. It is better than cleft grafting when there is only a short piece of the seedling left, because the ordinary cleft graft is more likely to get knocked out of the cleft during the season, while this kind of graft is fairly well protected by the stock. At about the surface of the soil, or slightly above it, a horizontal shallow cut is made with the saw, and a chip of wood is detached from the top of a slanting cut with the chisel, making a niche. On the shelf of the niche a cleft is made, in which two scions are inserted, the scions being cut as in ordinary cleft grafting, but thinner. The completed graft should be wound tightly to increase the pressure and hold the scions in place. The wounds should be covered with grafting wax.

GLAD I AM A FARMER.

"I'm glad I am a farmer,"
Sang the sun-browned lad I wed;
And with every tone,
And with eyes that shone,
Came truth of all he said.
"I'm glad I am a farmer,"
He sang it morn and night,
And his world grew gay
Day after day,
While the home-nest grew more bright.

"Yes! Glad I am a farmer,
The sturdy plow to wield;"
And he worked away,
The live-long day,
In garden, yard, and field;
Till his years had grown a-many,
And furrowed hand and brow;
Yet he sang the same
Old song of fame,
And he sings the same song now.

"Right glad I am a farmer,
I rejoice to tell it o'er;
For since I tried
Life's city side,
I love the old farm more!
Henceforth I'll stay a farmer,
And those who wish to,—may
Stay city-folk;
But 'tis no joke,
That I'll grow corn and hay."

—Nellie Hawks.

By Mrs. Minna E. Sherman, Fresno, Cal.

BUTTER MAKING.

THE farmer's wife making butter from one or two cows has difficulties to overcome that are not encountered in the creamery.

There are four ways of handling the milk for buttermaking. The first or primitive method of buttermaking was adding the milk to that already on hand and stirring down the cream until the whole mass was soured. Then churning it all.

This was merely following out the accidental discovery made by primitive man, that the milk in the skin bags when carried on the back of camels churns itself during the ride. This was rather an expensive way to produce butter and some ancient with nimble wits, reasoned out the wherefore. The expense was nearly as great as the first roast pig. If you have not read the story told by Charles Lamb in his inimitable way, better do so at once. It is fully as funny as Mark Twain's Jumping Frog.

Whole Milk.

When the whole milk is churned the result is a heavy loss of butter fat, as only the larger globules are saved. The smaller ones are held in the mass of curds. The buttermilk left is rich feed, but usually full of gaseous curds made by bacteria and it quickly turns rancid.

In order to secure as much of the butterfat as possible the churning of whole milk has to be done at a lower temperature than when the milk was skimmed and only the cream has been put into the churn.

Shallow Pans.

The second way is raising cream in the shallow pans. The pans are carefully placed in a cool room in the summer; in the winter a warm room is chosen.

The desirable temperature is about 60 degrees, and dryness rather than dampness is best. The pans should stand perfectly quiet for thirty-six hours when the milk under the cream will be clabbered.

Skim off the cream carefully. Take a silver teaspoon, slip the point of the bowl down close to the edge, holding the front of the spoon against the pan, then gently move the spoon along the edges pushing back the cream without disturbing the milk. Do not be an old granny and use your finger for this purpose as you may introduce bacteria enough to spoil the butter. It will certainly spoil the appetite, of anyone looking on, for the butter.

The ordinary flat skimmer is then slipped under the edge of the cream and it is lifted carefully and placed in the cream jar. When the skimming is finished stir the milk thoroughly into that already in the jar. The closer the skimming—the less milk in the cream—the better keeping will be the butter.

Deep Setting.

The third way was an improvement on the shallow pans as the milk was less exposed to taints and dust. The deep or gunshot cans were placed in cold water and the cream removed with a special dipper made for the purpose.

This did not produce a heavy cream and as a rule made no more butter than the shallow setting. The cream clings to the edges and sides badly, and it requires considerable experience to successfully skim clean. The deep setting undeniably made better butter than that set in any other way, for the best had not as yet come to the knowledge of the scientific world; this is the centrifuge?

Farm Separators.

The many taints of butter are controlled largely by using a separator, for it is easy to control the temperature of a small quantity of cream rather than a large quantity of milk.

The butterfat in heavy cream does not afford as great a medium for the bacterial action as the more watery milk. Before the days of separators the faults with butter made from unripened, or irregular ripened cream were numerous. This fault was usually blamed on the churn.

The American genius rose to the occasion. The Government Year Book makes the following surprising statement, that in the seventy years preceding the introduction of the separator that a churn was patented nearly ever twelfth day of the year. What might the average have been if a few had not been rejected no one will ever know! It was all unnecessary!

With the separator in use it soon was understood that the churn was of minor importance. If the churn was one that could be readily cleaned its actual shape mattered little. It was simply a concussor or mixer-up of the contents.

Ripening Cream.

When cream is ripe for the churn it has an acid taste that is agreeable when eaten on bread. The aroma is pleasant.

If the cream has been held at 60 degrees for two days, and is still sweet it should be helped to sour by the use of heat, lest some undesirable bacteria commence to work in it. Warm the cream by standing the jar in a can of hot water and stir slowly until it reaches 90 degrees, then cover for ten minutes and cool down slowly, in two or three hours it will be ready to churn.

Do not churn until the cream is smooth and acid and thick. Cream from pans rarely requires to be ripened, it is well if the cream is thick and acid to churn. Do not add any cream after the last twelve hours or the butterfat will simply remain in the buttermilk; take that last cream to start a fresh lot of cream with. It can be held in any form of pitcher until the cream jar is emptied, scalded and sunned for awhile.

Churning.

The butter should come in twenty or thirty minutes from properly ripened cream. When butter comes in five minutes the cream is over-ripened and the butter will go off its flavor quickly. While the style of the churn does not matter greatly, still a wooden one, if it is of the box or barrel type, is the best as it can be kept freer from taints. The wooden box type is to be preferred to the up and down churn; if these are used it is best to have it tin, not stoneware. The objections to stoneware are that I have had two women that always made gilt-edged butter suddenly have the butter become bad on them. In both cases they used the stone jar to hold the cream while gathering it for the churning. After hunting every cause possible for the badness of the butter I finally took home a pint of the cream from the pans and ripened it and churned it in the glass cream whip. It made fine butter that was good for fifteen days under ordinary treatment. Then we experimented and found that the stone churns were holding the bacteria. The second woman that had the trouble told her husband. He said, "Lets see," and took a hammer and broke up the jar when a large place was found that was porous, yet had no visible opening, but smelt foully of decaying milk.

Care of the Churn.

The care of the churn must be most careful. It should be washed, then scalded and dried in the open air, after having been used. Before using it again scald it and cool with water before putting in the cream. In churning, have the churn with less, rather than more, than its capacity. The speed of churning may be fast until the cream breaks, then if it is being turned by hand the admonition to turn slowly will be gladly obeyed.

When the butter is the size of wheat grains stop, draw off the buttermilk, letting it run through a strainer, put

in the plug and then add a liberal quantity of cold water in which a handful of salt has been dissolved. Rock the churn slowly from side to side, for a couple of minutes, to separate the particles of butter, let it stand a couple more minutes in all, take about ten minutes to this process.

Then let off the water, using the strainer to prevent loss. If the last of the water runs clear the butter is ready to take up. If not clear repeat the washing, but it should be clear if sufficient water was used the first time and the butter was in a granular mass, and not balled, by churning too long after it had gathered.

Working.

Take the butter up with the two ladles, for the hands must never touch butter if a gilt-edged product is to be made. Put the butter down lightly.

Shake a little salt on it as it is piled up. Work the salt in lightly at the rate of half an ounce to the pound; if the butter was washed in salted water. The less butter is worked the better, after the buttermilk has been dissolved out of it. The salt used should be fine, so it is better to sift it before using to remove coarse particles.

The butter can be churned salted if preferred, and in cold weather this is an excellent way; in the summertime the butter has often to be placed in the ice chest with the salt on it and not worked in until the butter hardens.

There will be no mottles on butter that is promptly salted from the churn, as it then contains moisture enough to dissolve the salt and not to have one globule of butter salty and the next without salt. Salt being a chlorine bleaches a trifle the globule of butter it clings to, while the one unsalted is the natural color; this makes the mottles.

CLEAN OR DIRTY MILK?

Very few are as careful about having everything about the dairy barn or milking shed as clean as it should be. Of course, but few cows in this State are kept in a stable even over night, so that they do not get into the filthy condition described by the editor of Modern Farmer, yet we fear that many of them are not as clean when milked as they should be. The item from the Modern Farmer is as follows:

We have seen some very filthy dairy barns lately and have been made to feel that milk is a very dirty thing handled as it is by many people. Overhead in a dairy barn is not a very good place for chickens to roost, especially if they go to roost before the cows are milked. A pail out of which cows are watered is not a very good thing to milk in. A cow that has both of her hind quarters covered an inch thick with filth cannot furnish clean milk. We have seen all of these conditions represented within a very short time, and this where milk was being sold to others. Of course, these are extreme cases, but are you quite sure that all the milk you use is clean and healthy? Think about it, and then go out and look the cows over, examine the barn and everything that the milk comes in contact with from the time it is drawn from the cow's udder until it is consumed, and see if there is not an opportunity for improvement even at "our house." Milk can be kept clean and sweet, but much of it is absolutely filthy and unfit for human food. It should not take one very long to get his regulation "peck of dirt" if he consumes some milk we have seen. It is no wonder that some people are sick; the greater wonder is that babies that are forced to live on such milk do not die off like sheep with the rot.

THE BEST LINE OF FARMING.

That this is true is very plain, unless we make an exception in favor of poultry keeping. From both lines of business there is an income every day in the year. The vicissitudes of weather and drouths have much less effect on the crop and all things considered it is certain that an investment in it is likely to be fairly profitable without much difference on account of wind or weather. The editor of the American Farmer says:

Dairying is the best line of farming because it best maintains the fertility of the soil, gives constant and steady employment and produces the best type of manhood. On the dairy farm we find better homes, better social and political development of mankind. The opportunities to the present day dairyman are many. The business affords great opportunity for improvements in increasing soil fertility, in securing better farm equipment and in breeding and selection of the working herd. The salvation of the country depends on agriculture and the foundation of all agriculture is the soil. Dairying is the greatest wealth-producing industry in the country and is needed everywhere, as everywhere there is a constant demand for dairy products.—Florida Agriculturist.

Lost Strayed or Stolen—One Cow

That is about what happens each year for the man who owns five cows and does not use a **Tubular** cream separator. He loses in cream more than the price of a good cow. The more cows he owns the greater the loss. This is a fact on which Agricultural Colleges, Dairy Experts and the best Dairymen all agree, and so do you if you use a **Tubular.** If not, it's high time you

did. You can't afford to lose the price of one or more cows each year—there's no reason why you should. Get a **Tubular** and get more and better cream out of the milk; save time and labor and have warm sweet skimmed milk for the calves. Don't buy some cheap rattletrap thing called a separator; that won't do any good. You need a real skimmer that does perfect work—skims clean, thick or thin, hot or cold; runs easy; simple in construction; easily understood. That's the **Tubular** and there is but one **Tubular,** the **Sharples Tubular.** Don't you want our little book "Business Dairymen," and our Catalog A. 200 both free? A postal will bring them.

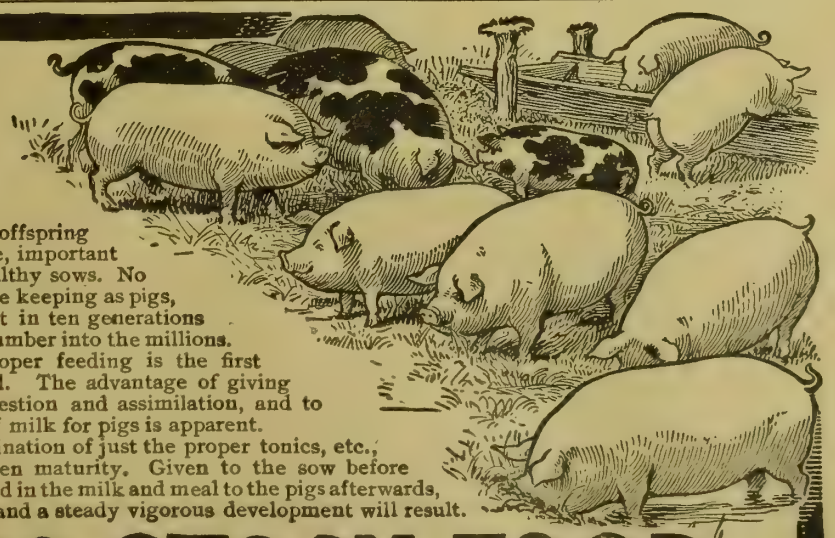
Vigorous Pigs



The sow is supposed to impart to her offspring her own constitution. It is, therefore, important that we raise pigs from vigorous, healthy sows. No stock will give as much return for the keeping as pigs, if properly cared for. It is said that in ten generations the progeny from a single sow will number into the millions. But disease must be avoided. Proper feeding is the first necessity and cleanliness the second. The advantage of giving a sow a tonic to insure proper digestion and assimilation, and to increase both quantity and quality of milk for pigs is apparent.

Dr. Hess Stock Food is the combination of just the proper tonics, etc., to produce perfect health, and hasten maturity. Given to the sow before farrowing, and up to weaning time, and in the milk and meal to the pigs afterwards, there will be no loss from disease, and a steady vigorous development will result.

DR HESS STOCK FOOD ATONIC

is the prescription of Dr. Hess (M. D., D. V. S.) and costs but 8c per month for the average hog of 125 pounds. It is especially intended to make market stock grow faster, cows give more milk and horses do more work. Besides this, it gives stock that sleek, healthy appearance that commands the fancy price. As proof that Dr. Hess Stock Food will produce the results we claim, we quote Professors Winslow, Finlay Dun and Quitman—the most noted of all medical writers—who tell us that bitter tonics improve digestion, that iron makes blood and nitrates of soda and potash assist nature in throwing off the waste material from the system. These are the ingredients contained in Dr. Hess Stock Food, and besides it is

SOLD ON A WRITTEN GUARANTEE.

100 lbs. $7.00 25 lb. pail $2.00
Smaller quantities at a slight advance.

Where Dr. Hess Stock Food differs in particular is in the dose—it's small and fed but twice a day, which proves it has the most digestive strength to the pound. Our Government recognizes Dr. Hess Stock Food as a medicinal tonic and this paper is back of the guarantee.

Free from the 1st to the 10th of each month—Dr. Hess (M. D., D. V. S.) will prescribe for your ailing animals. You can have his 96 page Veterinary Book any time for the asking. Mention this paper.

The Ornamental Garden

By ERNEST BRAUNTON

ARBOR DAY.

THE Department of Agriculture has issued an interesting leaflet on Arbor day, showing what the lesson of the day should be—the use and value of the tree in the life of the nation.

It points out that the tree which is significant is, of course, the forest tree as distinct from isolated specimens and advises that the best age to interest a child in forestry is between the ages of 6-7 or 13-14 when all such things as birds, beasts, flowers and trees appeal most strongly to the developing mind. A number of interesting topics are discussed from the muddy freshet, discolored by the soil the rain has dislodged, to the bursting blossoms and seeds of trees. Planting suggestions and the selection of a suitable day for Arbor day are also discussed and the interesting leaflet should certainly be in the hands of all who have anything to do with the training of children along these lines.

NORWAY SPRUCE.

The Norway spruce develops a straight, undivided trunk, with small slender branches which become somewhat drooping in later life.

In the open the limbs, extending almost to the ground, form a well-shaped, conical crown. The forest-grown tree retains its conical form, but the crown is much more compact and is restricted to the upper portions of the trunk.

In size, the Norway spruce is not unlike our red spruce. Trees 80 to 100 feet high and 2 to 3 feet in diameter are common in Europe on good situations.

This species is not indigenous to North America, but is a native of Northern Europe and Asia. It is almost invariably confined to cool, somewhat moist situations.

In Europe it ranges from the shores of the Baltic and the lower mountain slopes of Scandinavia to the Alps, where it occurs at an altitude of 6,000 feet. Planting has widely extended the limits of its distribution. It was introduced into England in the sixteenth century and in the United States has been grown as an ornamental tree for many years.

The possible planting range in this country is not yet fully known. As a rule, it will thrive throughout the entire Northeast and southward at the higher elevations. In the west favorable results have been attained only as far as the eastern part of the prairie region, and then only in the most protected localities.

PASADENA FLOWER SHOW.

The second annual spring show of the Pasadena Gardeners' Association opened April 4 in a large tent on North Fair Oaks avenue. The entries were numerous for all of the 71 classes and a very fine display was made, much superior to the first show held a year ago.

A feature of the show was the large cement tank in the center of the tent for aquatic plants, the usual greenhouse and other subjects being arranged on stands around the sides. In addition to $300 offered in prizes many special premiums were awarded. The show was kept open until April 6.

TRUE AMERICAN HOLLY.

Ilex opaca is an exceptionally beautiful native evergreen tree from the Southern states. The dark, glossy green leaves, with rough, crinkled edges and sharp spines, and the brilliant red berries form a strikingly handsome combination of color. One of the most sought-for evergreens for Christmas decorations.

THE SMALLEST TREE.

The smallest natural tree is the Greenland birch. Although its term of life is from 75 to 130 years, it seldom reaches more than ten inches in height under the most favorable circumstances. There are forests of these trees in Greenland half a century old and under five inches in height.

ROSE SOILS.

Where it is possible, plant roses in a soil underlaid with clay, or, if this is impracticable, select a moderately moist, compact soil. If these conditions do not exist naturally they can sometimes be made so artificially. Much can be accomplished in this direction, either by hauling clay, if the distance is not too great, or by incorporating humus in soil that is naturally loose.

In this connection, it may be well enough to mention that climbing roses often make the most desirable plants. They are almost always strong growers, while some of the finest varieties of bush-plants are rather slow growers. These climbing roses can, with a little pruning—and all varieties should be pruned each fall—be made to form excellent bush roses, if that form of growth is desired, or can be readily trained on a porch or trellis.

AMERICAN TRUMPET VINE.

Bignonia radicans is a strong-growing climber, which clings tightly to whatever its growing shoots touch. Forms a mass of green; particularly desirable for planting near old stumps, rocks or fences where it is desired to cover an unsightly object. Bears brilliant-colored small flowers in clusters during the summer months.

JAPANESE BARBERRY.

Berberis thunbergi is a dwarf-growing spreading plant with small, neat foliage and sharp thorns. The flowers are white and are followed by brilliant red berries in great abundance, during the latter part of the summer, which hangs on the plants throughout the winter. It is used for hedges and for planting in masses.

HARM DONE BY DODDER.

One of the latest leaflets of the Board of Agriculture and Fisheries of Great Britain deals with dodder.

The question to what extent the various species of dodder are harmful to agricultural crops is one which is of considerable interest to the farming community, and for some years past the agricultural press has contained many references to the prevalence of the pest in various districts.

Moreover, in 1905, as much as 11 per cent. of the clover seed samples examined by the botanist to the Royal Agricultural Society were condemned owing to the presence of dodder seeds, while two samples of red clover contained no less than 6 per cent. Some information, therefore, on the several species of dodder, the methods by which they are spread, and the best means by which they may be suppressed or avoided may at the present time be of value to agriculturists and seed merchants alike.

Various suggestions are made for prevention and remedy. Among these it is pointed out that where dodder is found infesting a crop, however small the patch, steps should at once be taken to destroy it. This may best be done by digging up the infested plants and burning the whole, in situ, by covering the area 6 to 9 inches thick with long chaff, sprinkling it with paraffin, and then firing it.

Tearing out the dodder with a rake is to be condemned, as this only serves to spread the evil. Infested clover or lucerne should not be fed to stock, as the seeds may pass through the alimentary canal unaffected, and Frank mentions a case in which a field was actually infected by means of manure from young cattle. In cases where the infestation is very extensive, covering the larger part of the crop, it is perhaps better to plough the whole under before seeds are formed. M. Garrigou called attention in 1904 to the value of calcium sulphide as a means of combating dodder and other parasites, and his experiments show that this substance is very clearly superior to sulphate of iron. It should be applied in the form of a powder when the dew is on the leaf. Above all, good cultivation in the widest sense should prevail, and all fields, hedges, and ditches should be kept clean and free from weeds.

The Vegetable Garden

By ERNEST BRAUNTON

GROWING ASPARAGUS.

BELOW we give two methods of growing asparagus, taken from "California Vegetables," by Prof. E. J. Wickson. The first is from a grower in the Santa Clara Valley; the second by an Orange county grower:

William Boot's Method.

Next March (for I think March the best month to plant in, all else being equal) choose a good piece of land, the very best is none too good, and plow just as good as you can.

I plow with four good horses on a single plow, and plow one foot deep, getting the land in as good condition as possible. Take a good team and draw furrows where the rows are wanted, going twice in the same place, just as deep as we can get the plow to run, throwing the furrow each way, making the distance six feet between rows.

Then carefully take up the plants, carefully separate them, for if they have been very closely grown they will cling together; spread out the roots as you plant them, clearing away all clods or anything that may hinder the growth. Plant not closer than three feet between plants in the rows. For field planting for the market by all means do not plant closer than six feet between the rows, and three feet apart in the rows; for if there is a plant that delights in plenty of room and air it certainly is asparagus. Cover the plants about two inches deep, and during the summer cultivation the pulverized earth will drop into the ditches, and by the time the season's cultivation is over the ditches or furrows will be nearly full, which finishes the first year in the field.

S. J. Murdock's Method.

The rows should be four feet apart and the plants eighteen inches from each other in the rows, and even more room would be better if the land is not too valuable.

After the ground is well plowed and finely harrowed mark out the rows the desired distance apart with a plow by going twice in each row, throwing a furrow each way from the center of the row, and from eight to twelve inches deep; then go one or more rounds in this with a cultivator closed up, so as to loosen up the soil well in the bottom of the row.

If you have any fine fertilzer put it in the row where you want to set your plants; mix well with the soil and set your plants over it. Place the plants in the bottom of the prepared furrow, spread out the roots and cover crown and all about two or three inches—the lighter the soil the deeper the plants should be placed—so as to secure the proper moisture till they begin to strike root.

After the planting has been done, take a light steel garden rake, or if the rows are even enough, we would prefer the wheel hoe with the rakes on, and stir the soil the whole length of the rows. Then, when the roots begin to grow and show themselves three or four inches high, the soil should be gradually hoed or cultivated to the plants till the surface is level. The ground should be kept moist, and in most localities irrigation will be found necessary to secure the best results. Do not neglect thorough cultivation, but after the roots begin to fill the ground do not work too deep, as there is danger of injuring them.

In the fall or early winter, when the tops have turned brown, the ground should be cleaned and all rubbish burned, for if delayed the seed will drop and get scattered, which will come up and may prove eventually to be the worst weed the grower will have to contend with, for if allowed to grow after once started it will soon fill the whole ground with a mass of roots, and very soon spoil the whole patch. As soon as the ground is cleared the whole field should be well cultivated, and coarse manure spread over the entire surface, so that the rains can dissolve and carry down the soluble plant food to the roots. As the period of rest here in our mild and warm winters is very short with this strong and persisting plant no delay should be indulged in furnishing the necessary plant food.

METHODS OF GROWING TOMATOES.

There are two methods in general use in the production of tomato plants to be set in the fields. The hotbed method is used entirely for early crops. Wooden boxes or frames so-called are set up upon a pile of fermenting material, usually horse stable manure, which is covered with an inch or two of rich soil.

The boxes are covered with glazed sash which are daily lifted to allow the plants a proper amount of air in order to produce stocky plants, which when three or four inches high, are transplanted into other frames of rotted manure and rich soil. No heating material is used in the transplanting beds; as with some night cover the sun gives sufficient heat. Plants are set four to six inches apart each way and are quite large by the time the weather is suitable for planting out. They may then be cut out with a four-inch block of soil and set in the field.

The other method of growing plants in the open air is simply a matter of selecting a suitable location, generally in the shelter of some big woods. The plot is carefully cleaned and prepared by plowing in a quantity of short, well-rotted manure. A quick acting fertilizer is then applied and chopped or raked in.

Pathways or alleys are marked, leaving beds about four feet wide upon which the seed is sown thinly broadcast. If plants come too thickly they should be thinned as they are weeded. Tobacco-bed sheeting or plant-bed cloth must be used to keep away flea-beetle which will do untold injury in the cool dry weather of early spring. These plants are pulled as soon as the weather is settled and set out with a peg or dibble on the prepared lists.

GROWING SEED.

To growers who save their own seed, and this may be profitably done in most cases, attention is called to the fact that careful notice should be taken of a few plants that seem to be just the type that is wanted and seed saved from these.

The practice of picking out all the large and finest fruits is not recommended, because very often when the fruit is large the yield is not proportionately so. An illustration of this occurred a few years ago.

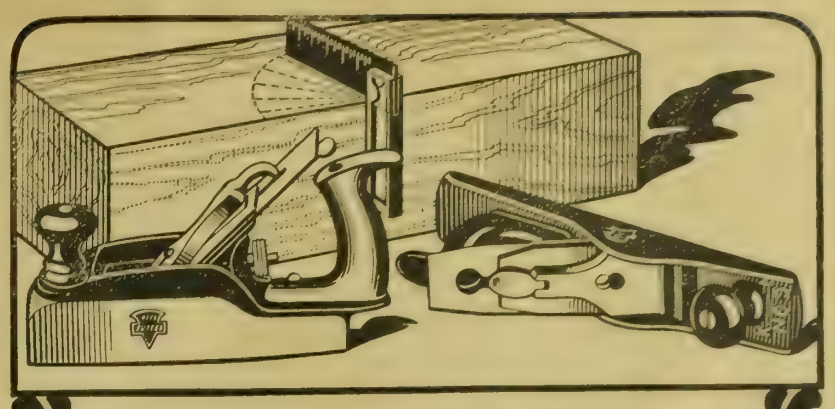
The tomato called "Enormous" was sent out. The plant was not at all branching, the stem and foliage being thick and heavy. The blossoms come in clusters of two, of which usually only one fruited. As a result the fruits produced were comparatively few in number but of large size, averaging throughout the season eight ounces apiece. This gave a yield of something less than two tons per acre. On the other hand, the variety "Freedom" which was small fruiting, but quite branching and free flowering in habit, gave fruits averaging three ounces in individual weight and over twelve tons per acre.

The necessity of care in the selection of the plant rather than the fruit is therefore quite apparent.

VEGETABLE SEEDS.

It pays to have good seed from good stock and if possible it will be well to procure the supply from the originator's own growing. There is no doubt that a variety which has passed from the originator's hands and into the hands of ordinary seed growers, who are not familiar with the ideal type as first selected, is sure to change it and perhaps for the worse. Therefore, if the originators are growers, try to get seed from them.

Jack's Mamma—There were three slices of cake in the cupboard, Jack, and now there are only two. How does that happen? Jack—It was so dark in there, mamma, that I didn't see the others.



True Tools

You can't square up a block with a lop-sided plane—saw straight with a buckled saw or bore a clean hole with worn-out bit. To do a good job you must have good tools. That's the reason men who have used and studied tools a lifetime insist on having

KEEN KUTTER

QUALITY TOOLS

They show their excellence not only in actual use, but at *first glance*—the "hang," balance, finish and careful adjustment being apparent. Keen Kutter Tools include not only Carpenter Tools but a full line of Farm and Garden Tools—Forks, Hoes, Shovels, Garden-trowels, Grass-shears, Rakes, Manure-hooks Pruning-knives. To get the best tool of its kind simply ask for a Keen Kutter. For 37 years Keen Kutter Tools have been sold under this mark and motto:

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

California Horticulturally

By JOHN ISAAC, Sacramento, California

PROF. WICKSON TO GIVE WAY.

IT IS reported that Prof. Wickson, who has been acting in the position vacated by Prof. Hilgard, as dean of the agricultural college at Berkeley, is to be superseded in that place by an eastern man, and naturally there is much dissatisfaction thereat. If an eastern man can fill the position to better advantage than can Prof. Wickson, then he should have the place, for California pays for, and should have, the best; but we must admit that we question very much whether any man from the east can give as good service as can a Californian in this branch of University work. Prof. Wickson has been connected with the University for many years, he has done much original work, and is authority on all matters connected with agriculture and horticulture. He understands the peculiar climatic and soil conditions of the state, and is withal a gentleman who has won the respect of all with whom he has come in contact, all of which should fit him for continuing in the position he has so capably filled for several years. Eastern men are accustomed to eastern conditions; it takes a long time for them to fit their minds to the changed conditions offered in California, and it seems worse than folly to turn out a man whom we know to be capable to make place for one who may not be. But as the University is now conducted it is questionable whether a Californian has any chance, no matter how competent he may be.

GOOD FRUIT PROSPECTS.

Later reports from the fruit sections are now coming in and, as we have stated, they are much more favorable than those which came in earlier and the indications now are that there will be a fair to good crop of all deciduous fruits. Even apricots, which will be lighter than most fruits, are showing up well in some sections. Cherries will be a good crop and prunes better than for years. Every season we have heavy rains or frosts at or about the blooming period and the newspapers always predict a total failure which later developments never fail to falsify. In over thirty years' experience in California we have heard these reports as regularly as the season, and have never yet known a failure of the fruit crop. True, there have been varying seasons, some much better than others; there have been seasons of shortage in some varieties, but never yet a failure.

LITTLE PEACH BLIGHT.

Peach blight which was very prevalent last season, and which caused much alarm, as many feared that it would be to the peach what the pear blight is to the pear, has not appeared so destructive this year. This disease has been known in California ever since we have been growing peaches, and some seasons it has proven very destructive, while in others it has almost entirely disappeared. It appears to be affected by climatic conditions largely, and some seasons are very much more favorable for its development and distribution than others. Unlike the pear blight, which is of bacterial origin, the peach blight is a fungus, and will vary in virulence with the season. It is more easily controlled than the pear blight, as it is external and within easy reach of remedies, the Bordeaux mixture applied full strength and early in the season, being found effective. It may be years before it will prove as destructive again as it did last year, but at the same time it is wise to take all necessary precautions against it.

PEACH CURL LEAF.

Curl leaf of the peach has again appeared and very much inquiry is being made for a remedy for it. There is no remedy when the leaves have curled. They are past redemption, although the progress of the disease may be stayed by proper spraying. Effective work against curl leaf must be done while the trees are dormant, and all such as are subject to the disease should be treated with full strength Bordeaux mixture during the later winter months. This may be followed up with a lighter application of the remedy when the trees are in leaf, but the effective work must be done early.

VINE HOPPER DROWNED OUT.

It is an old saying that it is an ill wind that blows no good, and it now seems that the high waters around Lodi and Acampo, which are the great table grape centers of the state, were not wholly an unmixed evil. For many years these vineyards have been afflicted with the vine hopper, which has devoured the foliage and deteriorated the grapes in quality and lessened them in quantity. It is now reported that while the vines are rapidly recovering from their involuntary baptism, the hoppers which hibernate in the ground have been largely destroyed.

A GREAT YEAR.

The year just past has been a most eventful one for California, and in the face of the greatest disaster the world has ever known, there has been a progress throughout the state that might be classed as phenomenal. According to advices received from all parts of California, it has been a year of advancement surpassing any previous year. While millions of dollars were lost in the disaster which came to San Francisco and other cities, and an almost unprecedented flood swept over the great interior valley, the state's population has materially increased, and development of agricultural lands has proceeded at an unprecedented rate.

Last year's fruit crop of all kinds was one of the largest known in years, and the outlook for the coming season indicates that with two exceptions similar conditions will prevail. While thousands of settlers of all classes have been pouring into the state the extraordinary demand for labor is still unsatisfied, and immediate employment for both men and women, could be given tens of thousands in all lines.

FARM MEMORIES.

One morning I was awakened with a strange new boy in my mind. It came to me at that moment with indescribable poignancy, the thought of walking barefoot in cool, fresh furrows, as I had once done when a boy. So vividly the memory came to me—the high, airy world, as it was at that moment, and the boy I was, walking free in the furrows—that the weak tears filled my eyes, the first I had shed in many years. Then I thought of sitting in quiet thickets in old fence corners, the wood behind me rising still, cool, mysterious, and the fields in front stretching away in illimitable pleasantness. I thought of the good smell of cows at milking. You do not know if you do not know! I thought of the sights and sounds, the heat and sweat of the hayfields. I thought of a certain brook I knew when a boy that flowed among alders and wild parsnips, where I waded with a three-foot rod for trout. I thought of all these things as a man thinks of his first love. Oh, I craved the soil! I hungered and thirsted for the earth. I was greedy for growing things.—American Magazine.

Under certain conditions, especially when checked in its growth by drouth, etc., growing sorghum becomes poisonous through the formation of prussic acid in the leaves. Great care should be exercised in letting stock have access to it at such times.

As a forage, sorghum contains an excess of carbo hydrates, or fat formers, and is best fed in connection with materials containing protein, or the muscle-making elements. The same fact is true of the seed.—Prof. Charleton R. Ball in Farmers Bulletin 246.

There are said to be 37 ways of cooking a steak, and every woman seems to know all but 36 of them.

With the Citrus Growers

By J. W. MILLS

EASTERN GROWN ORANGES.

A GROWER recently asked us if we thought that new hardy oranges that grow north of Florida along the Atlantic coast, will have any influence on the market for California oranges. To this we emphatically answered no.

What they now have may perhaps make a cheap substitute for lemonade material. The originators of these new citrus fruits never claimed anything else for them. Even if they were better than the originators claimed them to be, they never would take the place of the California or Florida orange and perhaps would never satisfy a fraction of one per cent. of the people who use lemons. There need be no fear that these new products will influence the market for the citrus fruits that are now supplied. They will be valuable in a small way only to use as a beverage for a short time during the year. It would appear that the short season in which they must grow would bring them past the season when such fruit would be most in demand.

NAVELS REBUDDED.

There was a great scramble a couple of years back to bud everything within reason (and some without reason) to Valencias. Fine Washington navel trees were in some cases budded to this variety and it has proven to be a bad proposition. The Valencia does not make a good tree when budded onto Washington navels in a great many cases. We have yet to see a good Valencia orchard that is now in bearing that has been built on a navel grove. It would be fortunate for those who have navel groves, if this condition were universal and everybody knew it. There may be cases east of the coast orange region where it may pay even to get a moderately good Valencia orchard in this manner, but we doubt it. Near the coast where the Valencia does its best and the navel is not so good as further inland, such a procedure may be the proper thing, but even then we doubt it. A vigorous growth from the navel tree after it has reached maturity seems to be the exception.

If citrus growers would study the climatic conditions which serve the different varieties best, and if they are in that particular locality which produces a good Washington navel, they should stick to it, no matter what prices other varieties are bringing. The higher the price the other kind brings, the closer they should stick to their favorite orange. There will be enough new plantings to equalize the run of prices before many more years pass. It takes time and money to get an orange tree into bearing and if it is then cut off and changed into another variety, several years are lost and more expense added. What may be gained should prices of the "other" kind remain high, will in most cases be lost by loss of time and attendant expense.

PRUNING ORANGE BUDS.

Do not allow the two-year old buds that form the tops of old transformed trees to become long and unwieldy. We have seen two-year old Valencia buds on old stocks, that had a growth of four or five feet with a little fruit maturing which bent the tops clear over, giving the trees a sort of umbrella shape.

Lemon trees may be trained in that manner in order to secure the Baronio system, but it is not in acocrdance with latest and most approved method of pruning orange trees. Such a growth was occasioned by not pinching back the tips of the branches during the first summer's growth. This is important and should not be neglected even if there were no danger of wind blowing them out. They are a rank growth that needs to be made thick in the stock with the main part of the head of the tree close to the stock so that it will hold up a heavy load of fruit.

No women should be expected to work for a husband after marriage. She usually works hard enough trying to get him.

TWO METHODS.

Prof. Hury W. Crockett, assistant horticulturist, of the Agricultural College, Logan, Utah, thus compares the two most commonly adopted systems of irrigation:

Flooding.

By flooding is meant the running of the water over the entire surface of the soil to be irrigated. This system is deceptive in that the amount of water retained by the soil is much less than is expected on account of the rapid evaporation following. At best the water is unevenly distributed and bad effects resulting from insufficient moisture are obtained. Unless the soil is of such texture that vertical percolation is very rapid it is very likely that it will not become soaked to a depth to be of the most use to the tree, and as the roots will always seek the moisture the result is that they will all grow near the surface instead of going down to a greater depth where they would naturally require fewer irrigations and be better able to withstand drought.

Furrow System.

In the furrow system the water is run in small streams in furrows between the rows of trees, the number of furrows being regulated by the size and age of the trees.

This method of irrigation is most successful where the soil is of such nature that the water will soak and spread laterally rather than vertically. The furrows should be so close to each other that the soil will receive a thorough soaking which will, of course, leave a dry surface between furrows. By allowing small streams to run for many hours the soil becomes soaked to a greater depth and the water is distributed more evenly than by any other method. The roots in search of moisture go deeper into the soil where a great amount of plant food is to be found. Experience will soon determine the size of streams to use, the distance between the furrows and the length of time required for a thorough irrigation. While flooding may be a faster and cheaper way of irrigating, it will be readily seen that the results obtained by the furrow system are greater proportionately, as it reduces the labor of cultivation to a greater extent, distributes the water more evenly, does not allow the water to come in contact with the bark of the trees, and produces more healthy, deep-rooted, vigorous and long-lived trees.

THE USE OF CUTTINGS.

Lemons, citrons, and limes are sometimes propagated by cuttings. Oranges and pomelos may also be propagated in this way, but as they do not root readily this method is seldom used with these fruits. As in other cases, the cuttings are taken from young wood, the twigs being cut into sections from 4 to 6 inches in length, and usually with a portion of one or two leaves remaining attached to the upper end. The base of the cutting is prepared by a smooth, slanting cut made with a sharp knife (a smoothly cut surface forms roots much more readily than a roughly cut surface in which the tissue is injured). Cuttings thus prepared may be planted in any convenient-sized box filled with sand. The basal end of the cutting is inserted in the soil, leaving about 1 inch of the upper end exposed. Wherever bottom heat can be secured, rooting is greatly facilitated. When the cuttings have sprouted and have attained a height of 8 inches to 1 foot, they may be transplanted to the nursery, as in the case of seedlings.

There once was a soldier quite thin,
Whose tongue hung away from his chin.
When asked what was wrong
He gulped loud and long
And said he was just mustard in.

After a man reaches 45, he is too old to buy anything on the installment plan that it takes more than 6 weeks to pay for.

Plant Your Trees This Spring

With plenty of water, this is the time of the year to plant

ORANGE TREES

The growth of a Valencia tree is worth $2.00 a year for the first five years. We have now ready for sale

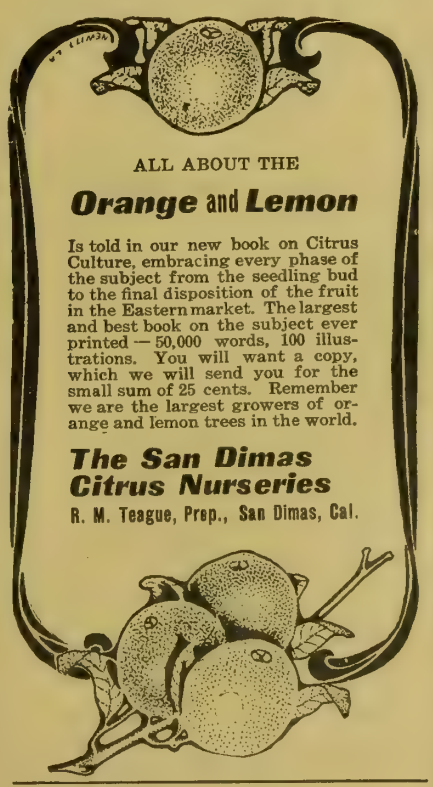
Works, 207-209-211 West Taylor St., San Jose, Cal.



ALL ABOUT THE

Orange* and *Lemon

Is told in our new book on Citrus Culture, embracing every phase of the subject from the seedling bud to the final disposition of the fruit in the Eastern market. The largest and best book on the subject ever printed — 50,000 words, 100 illustrations. You will want a copy, which we will send you for the small sum of 25 cents. Remember we are the largest growers of orange and lemon trees in the world.

The San Dimas Citrus Nurseries

R. M. Teague, Prop., San Dimas, Cal.

THE "BOSS" TREE PROTECTOR

Made of Yucca Palm

Is cheap, durable and quickly put on the tree. It prevents Rabbits from destroying your trees. A sure protection against frost, sun-burn, grasshoppers or dry winds. Can be easily removed; will last for years.

Send for samples.

PROF. WICKSON MAY RETIRE.

There has been a rumor current for a fortnight that Prof. Wickson, dean and acting director of the Agricultural College at Berkeley, is to retire at an early day.

It is to be hoped that this rumor is without foundation. Prof. Wickson has been so long and so intimately connected with the agricultural interests of California, that his retirement from active management of the agricultural interests of the College would be a little short of a calamity to the farmers of the state.

No less disquieting is the rumor that he is to be replaced by a man from the East. In the judgment of those well qualified to express an opinion, such a change cannot do other than work irreparable injury to the agricultural interests of California. No man from an eastern state can come to California with its entire change of climatic conditions, its soils, its methods of farming, and be of any value to the people for years to come. He may be a theoretical educator, he may understand general farming, as it pertains to eastern conditions, but he will not understand what is necessary to success in California. We trust, therefore, that Prof. Wickson will be allowed to remain at the head of the Agricultural College, where his influence for good is so wide and so lasting.

VALUE OF GOOD ROADS FOR HORSES.

The Department of Agriculture at Washington is lending its best efforts to promote the good roads movement in the United States. To this end a bulletin has just been prepared which is intended to show the value of good roads from the standpoint of either a breeder or user of horses. This bulletin shows that the total tonnage of farm products hauled on country roads in the United States is not known, but of twelve leading products it is estimated that nearly 50,000,000 tons were hauled from farms during the crop year 1905-06 at a cost of about $85,000,000, or more than five per cent. of their value at local markets. Of this traffic 40,000,000 tons represent the weight of corn, wheat and cotton, and the cost of hauling these three products was $70,000,000. The number of working days taken to haul twelve leading crops from farms to shipping points during the crop year 1905-06 is estimated at 21,417,500 and the number of loads taken as 30,319,000. The greatest time for any one crop in hauling to shipping points is 8,494,200 days for corn, but if the time taken for hauling to local mills the wheat consumed in the counties where grown be included, the total number of working days taken for hauling wheat from farms during the crop year just mentioned would be over 8,900,000. Although there were fewer loads of cotton than of oats, it required 1,000,000 more working days for men and teams to haul the fiber than this grain. The average time for a round trip for hauling oats being 0.6 day and for cotton one day. The greatest distance over which it will pay to haul a given crop will practically limit the production of that crop for the market. Beyond that limit a more valuable product must be made. Cotton is hauled a greater distance than wheat, and wool is hauled on an average more than three times as far as wheat and more than three times as far as cotton.

Live animals are often profitable substitutes for crops on lands remote from shipping points, for the animals may be driven at an expense far less than the cost of wagon transportation. The distance limit for profitable farming for a given crop may often be extended by improving the methods and means of hauling. Better wagons and horses may be used, roads may be improved and better facilities may be had for receiving the products at local markets and shipping points. Improvements of this kind tend to lessen the expense of hauling a load and thus make it profitable for farmers to haul from greater distances. From tables in the bulletin in question it is said that average loads of the same product weigh in some states twice as much as in others and consequently the expense of hauling is much less in the former states than in the latter for similar distances. The average distance from farm to shipping point for 21 of the 23 products treated in this report range from 7 to 12 miles. When these significant facts are taken into consideration one begins to recognize what the value of good roads will be when they shall have become general That it will require the expenditure of an almost incomprehensible sum of money to bring about that result is true, but that the bettered conditions will be worth the cost is beyond question.

CULTIVATE THE APPLE.

There is no fruit more universally liked, or more generally used, than the apple, and in addition to its health giving qualities, there is none more valuable for planting for commercial purposes, on account of its long market season and for its so-called secondary products.

By reason of the peculiar topography which gives to many portions of California the entire range of climate on the Atlantic coast from Maine to Florida, also gives us the advantage of having the apple as a dessert fruit every month of the year.

Everything about the apple can be utilized. If not used as dessert fruit, it can be cooked in many attractive and palatable forms, dried or made into beverages, butters, jellies or finally used as feed for stock, especially the sweet apple which is said to be excellent for fattening purposes. Even the cores and peelings, according to a recent circular from a United States Consul, are now wanted for shipment to Europe to be used for various purposes.

In fact there is no other product of the farm that so thoroughly fills the old German farmer's idea of a money maker. When asked how it was that he had risen from poverty to comparative wealth in such a short time, replied "that he had worked hard and produced many things on the farm which he took to market to sell; what he could not sell he brought back and fed to his pigs, and what his pigs could not eat, he himself ate."

There is a very general revival of interest throughout the fruit growing sections of the world, where apple culture is possible, in this industry, and much attention is being given to the introduction and testing of new varieties and to more thorough methods of cultivation. Extensive plantings are made in localities where in former years it was thought the apple could not be grown, for with improved means of transportation and of keeping, can be sent in good shape to all attractive markets of the globe. Even in old England large plantations are being made for commercial purposes, mainly to supply the increasing demand of the Englisn market. Rivers & Son, the eminent horticulturists of that country, are authority for the statement that orchards planted in apples upon land properly cleared, drained, trenched and fenced against game and stock, will pay a fair profit upon the capital invested and labor required to produce a crop, and will increase in profitable income for a number of years. There is no fruit tree that responds so faithfully and promptly to systematic and intelligent treatment. As an instance, one of the bad effects of neglect is the habit acquired by nearly all orchards of bearing an excessive crop one year and nothing, or next to nothing the following year. Mr. Pell, at one time the famous grower of the Newtown Pippin at Pelham, N. Y., more than thirty years ago, showed to the fruit growers of the country that by judicious but persistent thinning of the fruit each year and the use of fertilizers, it was possible to break up this habit of overbearing, and in his orchard of 2000 trees he succeeded in making them abandon the off year system and give him annually uniform crops of magnificent fruit.

What is needed in Southern California, and in fact in most portions of the state, is to more fully recognize the peculiarities of our climate, and that we have three zones in which the apple can be grown, viz., the Coast region; the interior valleys, lower foothills the upper foothills and mountain valleys and plateaus up to 3500 to 4000 feet.

These all require a careful selection of varieties and different treatment of the trees, especially in locations where irrigation is necessary.

The custom of planting the apple among citrus trees or of growing any crop that requires winter irrigation or cultivation should be discontinued.

PICKLING OLIVES

Continued from First Page

few treatments with pure water before being put finally into brine.

The first salting must be done very gradually and carefully, in order to prevent shrinkage and wrinkling of the fruit. For this reason, gradually increasing strengths of brine must be used, as described, and the olives left long enough in each to be thoroughly penetrated.

In these operations no sign of scum or slime should be allowed to accumulate on the olives, the vats or the covers. This is of especial importance during the treatment with plain water. On the first signs of sliminess around the sides of the vats, where it appears first, the latter should be emptied and thoroughly brushed and scalded before replacing the olives.

The best pickled olives are made without the use of lye, but this process is only practicable with olives such as Ascolano and Columbella, the tartness of which is easily extracted, and where the water is extremely pure and plentiful, and even then it is very slow and tedious. It differs from the last process only in omitting the preliminary lye treatment. The olives are placed from the beginning in pure water, which is changed twice a day until the bitterness is sufficiently extracted. This requires from forty to sixty days or more. The extraction is sometimes hastened by making two or three shallow, longitudinal slits in each olive; but this modification, besides requiring a large amount of expensive handling, renders the fruit peculiarly susceptible to bacterial decay and softening.

In a recent issue of the Cultivator appeared a road grader, known in the market as the New White City Grader, which is becoming popular because of its cheapness. It costs $125 delivered, can be worked on sandy ground with one team, and Mr. Schilling, the general agent says can be run where heavier graders will not do the work. We trust this grader will fill the want of much men and towns, and revolutionize road building in California.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

About a thousand acres of beets are planted in Chino.

Cabbage shipping from the Fullerton belt is now well under way.

The Imperial creamery is now making about three-quarters of a ton of butter a day.

On Thursday night a trainload of cattle were taken to Piru and put in pasture in the canyon.

James Irvine of the San Joaquin ranch shipped five carloads of fat cattle to Los Angeles Monday.

Fuller Bros. received this week a car of corn from Kansas. They also received one last week at Heber.

Reports from Imperial are to the effect that much vegetation has been destroyed by the cuts worms there.

Milking machines are being installed on the ranches of J. D. Huston, of Imperial and W. E. Wilsie, of El Centro.

If present favorable conditions continue, the amount of beets planted for the Chino factory will be 10,000 acres.

Southern growers are receiving $20 a ton net for cabbage and say there is good money in the industry at this price.

The first shipment of summer squash from the Imperial valley was made on April 22, and came from Brawley.

The registered Holstein-Friesian bull, Admiral Togo of Compton, was sold by J. M. Spencer to R. B. Harper, Downey.

The Escondido shipments for the week were 7050 dozen eggs, a ton of poultry, 40 cans of cream and 1257 pounds of butter.

Dried eggs are being handled for the market by a Santa Barbara man, F. A. Martin, one of the old-time residents of this city.

It is probable that considerable Indian or field corn will be raised at Brawley this season, the planting time coming about the first of August.

It is estimated that the total output for the season, including all varieties of oranges, lemons and grapefruit, will be close to 1500 cars.

Thus far this week six carloads of graded Holstein and Jersey cattle have arrived in the Imperial valley and have been placed on the ranches.

A twenty-five acre orange orchard, 15 acres in full bearing, and 10 acres in one-year old trees, has been sold to D. A. Kingsbury at Hemet for $17,000.

Summer squash promises to be a profitable crop on the desert and the shipments from Brawley alone will amount to nearly a carload the present season.

It is possible that another year will see shipments of cucumbers and squash from the Imperial valley sent to Chicago and other eastern points in carload lots.

Hemet is showing steady growth this season. About 1000 acres are being planted to fruit, 300 acres to walnuts, 200 to oranges, the balance to peaches and apricots.

Four carloads of cabbage were shipped from Anaheim today. The output has averaged a carload daily the past week. The shipments will be heavier in another week.

The experiment made some months ago of bringing shelled corn from Kansas to the Imperial valley with which to harden hogs and cattle before shipping them to the Los Angeles market is being followed up in a quite extensive way.

The ranchers about Arlington are meeting with more or less adversity this spring, especially those who have alfalfa, as the weather hindered and the rain spoiled to a great extent the first crop. Now the worm pest is here again.

F. H. Stanley reports that the Brawley cantaloupe crop is in splendid condition. He says the fields are being better cultivated than ever before, the growers having learned by experience how to care for them. The season is fully two weeks ahead of last year and the vines are well set.

HORTICULTURE.

In West Highlands the Citrus association has about 75 cars yet to ship.

The price of oranges is holding up well. The local price for a single box is now $2.

In the cities the cut worms are general feeders, and attack anything from flowers to fruit trees.

In East Highlands it is estimated that there are close to 130 cars yet to ship of navel oranges.

Parasites for the purple, red and black scales are at work in the orchards of Southern California.

James Waters of Colton recently sold his ten-acre lemon grove, south of the railroad there, for $10.000 cash.

The estimate of Riverside's total orange crop this year is 5000 cars. Of this amount 3000 cars, in round numbers, have been shipped.

Slowly the remaining navel oranges in the south are being moved. Too slow, as has characterized the fruit shipping industry the past two months.

Hot house cucumber vines in Southern California have been troubled with a powdery mildew. This is quite easily controlled by using Bordeaux mixture.

In sections of the Imperial valley during the last few days an army of worms has been busy, and quite a little damage has been done in spots to alfalfa and grape vines.

As the season advances, orange growers who still have navels and seedlings on their hands are growing apprehensive about the prospects of getting cars to move them.

E. A. Parrish, superintendent of the Wild Rose ranch in Temescal canyon, has set out 20,000 eucalyptus trees this year, in addition to a peach orchard, says the Corona Independent.

A rancher living between Colton and San Bernardino took in to the Horticultural Commission some specimens of oranges from his place that had been attacked by the army worms.

In the apple sections of the south power sprayers have been in use for ten days spraying for powdery mildew, and this will be followed by arsenical mixtures for the codling moth.

Rivera reports good prospects for a big walnut crop and good prices. Chino, too, will soon become a famous walnut section judging from the rapid increase of acreage in that direction.

The purple and red scale parasites which were brought to this state last winter by George Compere from China are being propagated in the orchards near San Diego, where the scale is the most troublesome.

The railroads are failing to make good their promises of plenty of cars, and the feeling is growing among Riverside and Redlands orange men that they have been discriminated against in the allotment of cars.

The fruit raisers of Tustin are determined to make an effort to protect their orchards from the general public who it seems has concluded that it is perfectly right and proper to go into orchards and carry away fruit at will.

The shipments of oranges and lemons from Highland, East Highlands and West Highlands to date totals 1210 cars, of which Highland shipped 559 cars, the western end of the township 250 and East Highlands the remainder.

The Westfall Fruit Company reports the sale of a part of a car of navels in New York on April 19 for $5 per box, the record price of the season. The fruit was shipped by W. F. Whittier, who is largely interested in Hemet, from his grove at Redlands Junction.

Cut worms are very much in evidence in San Bernardino again and in some portions of the valley they are again attacking the orange trees, eating into the ripe fruit where it is still on the trees; but the worst damage is to the young fruit just setting and to the foliage.

Northern California

AGRICULTURE.

Plans are on foot for the building of a beet sugar factory by Los Angeles capitalists at Corcoran.

A Kings county farmer sold some hogs in the open market Friday that brought him $34 each.

Within the past year several carloads of horses and mules have been shipped from the Wheatland section.

From Anderson last year there were shipped by rail points agricultural products and stock valued at $800,000.

Crops of all kinds in Solano county are looking well. Hay promises to yield well and grain will average a good half crop.

A movement is under way to organize a reclamation and drainage district which will include the greater portion of Sutter county.

Hay was bringing a fancy price at the Hollister warehouses this week. One particularly fancy lot sold for $26 per ton on the cars.

J. M. Daggs of Hanford sold three Duroc hogs Friday at 7 1-4 cents a pound. The three weighed 1465 pounds and brought $102.43.

The agricultural, horticultural and stock-raising sections of Shasta county are rapidly forcing their way to the front. A few years ago all was mining.

Frank H. Burke sold to H. S. Hersman, San Martin, the two registered Holstein-Friesian cows, Frolis of La Siesta and Donzella of La Siesta.

J. H. Williams has sold the registered Holstein bull, Sir Josephine Thorn, to Jas. M. Wann, Porterville; and Sir La Reina Josephine, to H. S. Halsel, Porterville.

The fruit-growers of the Suisun valley are considerably exercised over the labor problem and men who want work in the orchards will be welcomed to this valley.

About thirty chicken raisers, owning in the aggregate about 9000 chickens, attended the meeting of the Poultry Raisers' Association in Santa Cruz Saturday morning.

The farmers will hail the advent of warm weather with delight, as it helps to cure the first crop of foxtail and alfalfa hay, which is now being cut. —Hanford Sentinel.

An irrigation company desires to submit to the property owners within the confines of Tulare lake a proposition for the drainage of said lake for a period of 50 years.

The deliveries of beets from the Pajaro valley will probably be completed this week, but it is impossible at this time to say when the deliveries will be closed from the Salinas valley, or when the factory will close down for a general clean up.

There will be a good crop of all varieties of fruit in Solano county. Pears have set well and the prune trees are loaded again this year. As a general average the peach crop will be splendid. Clings were cut by the rain at time of their blooming, but the other varieties more than offset their shyness.

HORTICULTURE.

Lindsay is beginning early to plan for the next citrus fair.

The olive trees of Kings county are simply loaded down with fruit.

A successful traction engine has been built and is now running in the orchards around Winters.

The Chico fruit plant is preparing for extensive business during the coming drying and packing season.

Early apples in the eastern part of the Pajaro valley will not make much of a showing even with continued sunshine.

A big lot of lumber is already on the site for the big new winery at Armona and the structure will soon commence to arise from the ground.

Of the Solano county fruit, almonds and apricots are almost a total failure, but cherries, peaches, pears, plums and prunes will produce a fair crop.

The big cannery associations have had their representatives in the northern field this week, and a few sales of apricots at $60 are reported.

The first run of the Marysville cannery will be on plums and peaches, and if the crops are up to expectation the run this season will be a record breaker.

The first batch of beneficial insects that will be sent out from the state hatchery by the Horticultural Commission will be the parasite of the brown apricot scale.

A tour of inspection through a portion of the Pajaro valley developed that the Bellefluer apple outlook is excellent, the trees being heavy with well set blossoms.

A grower of winesaps near Watsonville states that scab is in evidence and doing some damage. Newtowns promise better than a fair crop and other varieties fair.

T. J. Brundage of Farmersville recently as an experiment planted several pomegranate trees on a piece of black alkali land and the trees are not only growing but doing well.

Farmers around Knights Landing are greatly discouraged over the crop prospect. A very small acreage of grain was sown owing to the continued rains, and the greater part of it was sown very late.

The vineyards around Hanford are putting out new shoots and a fine crop of raisins is in prospect. Many buyers are in the market but not many crops are being sold, even at the prevailing high prices.

The work of cultivating the Tulare county vineyards is progressing, the weather being favorable for drying the ground, which has been very wet this season, and the work of cultivation greatly retarded.

Since the danger point for fruit from frost is about passed, it is safe to predict the outlook around Woodland is promising. There will be a good yield of peaches and pears. Prunes are also well set, but it is most too early in the season to tell what the yield will be. The indications, however, are that there will be a good crop.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clork Exposition."

Profit in the Poultry Yard

By Mrs. A. Basley, Hollywood, Cal.

HELPING A NOVICE.

A CHAT with my sisters in the poultry yard this week about a beginning in the chicken business may prove interesting to some of the older raisers and helpful to novices.

A Voyage of Discovery.

I often wish I were a beginner, as I remember the enjoyment of seeing the little chicks hatch under their mothers, and watching my grandmother's cook float the eggs, two days before hatching time to see which eggs contained a live, healthy and "kicking" chick. How those eggs used to bob about on the warm water, and then they were carefully replaced under the wrathful hen who scolded loudly at being disturbed so ruthlessly.

There was such delight in watching the "biddies" with their broods and learning the dispositions and characters of the different hens, for the character of hens varies as much as the character of each individual human being; some are cross, others kind and gentle like doves, some are nervous and restless, others lazy and indifferent; some good, affectionate mothers clucking to and feeding their chicks and never losing one; others cross and spiteful, treading on the chicks and fighting with their neighbors. There is a difference in the disposition of hens and of human beings.

Helping the Novice.

"Will you come and help me to lay out my chicken yards?" wrote a young and beautiful girl last week, "for I want to make a success of the chicken business and it will be easier to do so if I begin right."

I often go to ranches to mate up the fowls, or to select the best breeders or investigate trouble of some sort, as well as to plan yards and hen houses and organize the operation of different plants, and I was glad to be able to go into the country to help my unknown friend.

It was one of our loveliest days and the site one of California's choicest and most beautiful locations at the foot of the Sierra Madre mountains. The soil a "dessicated granite," a rich, gravelly loam full of tiny grit that would never pack hard but would give excellent drainage, supply the hens with grit and keep their feet and shanks in good condition, as I explained to my new friend.

Soil of this kind plays a very important part in the health of fowls and if you have healthy fowls your venture will be more than likely to pay. An ample supply of the purest mountain water was also a recommendation, for pure water and good air are quite as necessary for fowls as for human beings. Soil, water and air good, and plenty of fruit trees for shade. "You have an ideal location for a poultry ranch!" was my exclamation.

Planning the Yards.

The yards we planned should be about twenty-five feet broad by about seventy-five long, each to contain at least two trees for shade for the fowls and each a faucet of water. The trees appear to be about eight years old and spread enough to give shade, but are not too thick; there will be plenty of sunshine also.

The henneries are to be double houses on the dividing line of the fence so that it can be used either as one large house or two small ones, and opening into either or both yards. The land lies on a gentle slope, and one might be tempted to have a wooden trough of water, kept always running through all the yards, but I knew a man who had three thousand hens and who was forced out of the poultry business in California by such an arrangement. He bought some new pullets and although he had never had roup on his place these pullets brought it in and the running water carried it through all his pens and it resulted in his having to go out of the business entirely.

No one who has not been in the business knows how it lightens the work to have the water piped into the pens. It is quite hard for a woman to carry a bucket of water to a number of pens, besides having the water in each yard the trees can be easily watered and even the yards themselves. I found in some places where the soil baked, that by having the water arranged so that the yards could be irrigated, that the soil could be turned over or ploughed even in the heat of summer, and so kept healthy and clean.

A Good Start.

My new friend had been ordered to lead an outdoor life, and loving chickens and all young things was making this venture as a health restorer as well as an investment, and I have but little doubt of her success in both respects.

Her next request was to come out and see the hens that were sitting. She had them nicely arranged in good sized coops or nests with rainproof tops or small roofs, and an opening so that the hens could come off to eat, drink and dust themselves. I told her that she should have a can with a perforated lid like a pepper pot and once a week she should stroke the hen down the back, which will make her spread her feathers to show her anger, and whilst the feathers are standing out she must pepper the insect powder well into them.

Then I asked her if she had tested the eggs, she replied that she did not know how to do so. Egg testers are sold at all of the poultry supply houses,

BUFF WYANDOTTES

None Better for Beauty and Utility

In hot competition at Breeders' L. A. Show took more prizes than all my competitors combined.

O. S. Hofmann, San Jacinto, Cal

but not having one I rolled up a poultry magazine, tied a string around it to prevent it unrolling and using it like an old fashioned telescope, I placed an egg at one end and my eye at the other, and tried to look through the egg, most of the eggs were fertile and these appeared as if three-fourths filled with ink, but in one of the eight nests all the eggs were perfectly clear.

These eggs were from her favorite hen and she was much disappointed when I told her that there were no chickens in them. I broke one to show her that there was nothing but "egg" inside it and that the only thing she could do was to boil those eggs for her other little chickens. It occasionally happens, that a hen will lay only infertile eggs. Sometimes by mating her to another male bird or changing to several there may be found one that will give fertility, but occasionally there are hens that never lay a fertile egg. I have had two, one of them I bought to bring in new blood, she laid every day in one month for she was a good layer but I never found a fertile egg; she was a very high-priced bird but of no use for a breeder.

Hen or Incubator.

Then up came the question as to which would be the best, to begin with hens or with an incubator.

An incubator she must have later in the season or I should say at the beginning of next season, for hatching time for a novice is nearly over and she will have better "luck" at this time of the year in bringing her chicks up with hens, in those nice yards under the shade of the trees, than in a brooder, and also being a novice she can study her hens, learn the way they mother the chicks and be ready next fall and winter when the hens do not want to sit to "mother" her incubator chicks in the brooder.

She will have learnt by watching the hens, to understand the baby chicks, differents cries and notes and will know their wants and wishes as if by instinct. So I advised her to wait a little before investing in an incubator. "How many brooders should I have, will one be enough for one incubator?" she asked. As she intends to get a 200-egg incubator I told her that when I was operating only two incubators I found that I needed twelve brooders and that she should have from four to six, and I explained why the crowding injured the chicks and stunted their growth and killed so many. It is better to have plenty of brooder room; it pays to bring up the chicks right.

Supply of Green Food.

"What shall I do for green food? Had I better have a small alfalfa patch as well as the lawn?"

Nothing is better than green alfalfa for the hens and chicks, but as you have not commenced to plant one you will not have it ready for this early summer, so I advise you to plant one patch of kale; this grows quickly and by taking off the outside leaves it will keep on growing until it is higher than your head. The hens are exceedingly fond of kale; kale is a species of cabbage. They also like "Swiss Chard"—this is a sort of beet—and a patch of this would make a good change with the kale. "How large should these patches be?"

That would depend upon the number of hens; with twenty-five to thirty each patch might be about twenty feet square. I would also plant some lettuce for the little chicks; it is very nice for them and you could use some of it in the house.

I found that by planting a few boxes like the florist's seed boxes, with lettuce, that the brooder chicks were made very happy on stormy days when they could not go out. They did enjoy pulling up and eating the little lettuce plants, I suppose they thought they were in mischief and it really kept them out of mischief. Little brooder chicks get naughty and learn bad habits if they are not kept busy. I have a letter before me now telling of some chicks that are perfect little cannibals; they tear each others insides out. This comes from their not having to work, so I try to keep mine busy and happy.

Chas. E. Smith Breeder of *Arrowhead Strain* of

Barred Plymouth Rocks

Won at Los Angeles Show, the largest ever held on the Coast, 225 Barred Rocks in class, as follows: 1st, 2nd and 5th Pens; 1st, 3rd, 4th and 5th Hens; 1st, 2nd 3rd and 4th Pullets; 2nd Cockerel. Barred Rock Club Cup for Best Display; Association Cup for Best Display, and Three Incubators, one for Best Pen in Show, all breeds competing.

Choice Stock for sale from same mating that I bred my prize winners from. Prices reasonable. Eggs, *$3* and *$5 per 15.*

CARE OF CHICKS.

Our little chicks all come from the incubator, so that will have to be my start. When the machine begins to hatch we close it up and watch and listen to the "cheep, cheep" of the little ones.

The door is only opened to see about the temperature. In about twenty-four hours we open the doors and take out the little downy babies, placing them in the boxes, fifty to a box, and cover with a woolen cloth, setting in a quiet, warm place for another twenty-four hours.

Then comes the first feed. We place the little babies in a large box that has a good newspaper carpet, leaving some little shallow water cups in it. We feed some hard boiled egg, shell and all, mashed together with some millet seed and cracked or rolled oats. Just a little of this feed, for they are babies and are soon put back in their own box that has a good newspaper carpet. Newspapers are so plentiful and convenient, one can change and burn the old papers often. We keep the little babies this way for several days, till they begin to be lively, then they are transferred to their yard in the back yard.

Their coops are roomy, floored to keep out rats and other lovers of baby chicks. Before putting them in they are cleaned well and given a good airing. We use Beaumont oil a good deal with coops and houses, but too much must not be used or it will blind the little chicks. Carbolic acid is good, too.

The chicks' yard is made my standing twelve-inch boards on the side. This keeps them in until they are old enough to run abroad, and shields them from the cool spring winds. In the middle of their yard they have their feeder—four posts, driven into the ground, and covered top and sides with mesh wire, the meshes being large enough to let the chicks pass in and out till they are six weeks old. The coops are cleaned thoroughly every week as long as the chicks are there.

Our feed is all dry—millet seed, cracked corn and wheat—till they are large enough to take the whole grain. We feed all they will eat, and supply good, fresh water. The water is in iron drinking dishes, and is given fresh three times daily in hot weather.

The chicks grow like weeds. In two weeks they are over their yard fences and wander at will over the yard. As they get older they go farther. When they are small we feed them three times a day, but from two weeks old we only feed them twice a day, putting plenty in the feeder, and they can go to it when they please.

As soon as our chicks are well feathered out, we like to put them in their house. We think they are easier to move then, and they need more room. We separate the cockerels from the pullets, and keep them in a separate pen, but all the laying stock and young chicks have unlimited range and clean quarters. So far we have had very little disease. Sometimes a few of the little early chicks will droop and die from chill, but cleanliness and plenty of feed will raise the most of them. We have very little dew in the mornings, but when there is, we hold the little ones in the coop awhile. Generally they are out very early. Chicks want to be out as early as possible. They are ideal rustlers.—Commercial Poultry.

What was it Franklin said? "If you'd have a thing well done———'" "Tell your cook you'd like it rare," interrupted Subbubs.

Malthoid Roofing

is 32 inches wide and one roll will cover 200 square feet. It is easier to put on than laying a carpet. Makes a durable and lasting roof, absolutely impervious to heat or cold.

ALCOHOL AND GASOLINE.

Farmers' Bulletin No. 277 of the United States Department of Agriculture is on the use of alcohol and gasoline in farm engines. After describing the use of both substances, the following conclusions are reached:

The conclusions regarding the use of alcohol as fuel for engines as compared with gasoline are based on the preliminary results of the department's experiments and investigations, and upon the general knowledge of the authors:

First—Any engine on the American market today operating with gasoline or kerosene can operate with alcohol fuel without any structural change with the proper manipulation

Second—Alcohol contains approximately 0.6 heating value of gasoline by weight, and in the department's experiments a small engine required 1.8 times as much alcohol as gasoline per horsepower hour. This corresponds very closely with the relative heating value of the fuels, indicating practically the same thermal efficiency with the two when vaporization is complete.

Third—In some cases carburetters designed for gasoline do not vaporize all the alcohol supplied, and in such cases the excess of alcohol consumed is greater than indicated above.

Fourth—The absolute excess of alcohol consumed over gasoline or kerosene will be reduced by such changes as will increase the thermal efficiency of the engine.

Fifth—The thermal efficiency of these engines can be improved when they are to be operated by alcohol, first by altering the construction of the carburettes to accomplish complete vaporization, and second, by increasing the compression very materially.

Sixth—An engine designed for gasoline or kerosene can, without any material alterations to adapt it to alcohol, give about 10 per cent. more power than when operated with gasoline or kerosene, but this increase is at the expense of a greater consumption of fuel. By alterations designed to adapt the engine to the new fuel, this excess of power may be increased to about 20 per cent.

Seventh—Because of increased output without corresponding increase in size, alcohol engines should sell for less per horsepower than gasoline or kerosene engines of the same class.

Eighth—The different designs of gasoline or kerosene engines are not equally well adapted to the burning of alcohol, though all may burn it with a fair degree of success.

Ninth—Storage of alcohol and its use in engines is much less dangerous than that of gasoline, as well as being decidedly more pleasant.

Tenth—The exhaust from an alcohol engine is less likely to be offensive than the exhaust from a gasoline or kerosene engine, although there will be some odor, due to lubricating oil and imperfect combustion, if the engine is not skilfully operated.

Eleventh—It requires no more skill to operate an alcohol engine than one intended for gasoline or kerosene.

Twelfth—There is no reason to suppose that the cost of repairs and lubrication will be any greater for an alcohol engine than one built for gasoline or kerosene.

Thirteenth—There seems to be no tendency for the interior of an alcohol engine to become sooty, as is the case with gasoline and kerosene.

Fourteenth—With proper manipulation, there seems to be no undue corrosion of the interior due to the use of alcohol.

Fifteenth—The fact that the exhaust from the alcohol engine is not as hot as that from gasoline and kerosene engines seems to indicate that there will be less danger from fire, less offense in a room traversed by the exhaust pipe, and less possibility of burning the lubricating oil. This latter point is also borne out by the fact that the exhaust shows less smokiness.

Sixteenth—In localities where there is a supply of cheap raw material for the manufacture of denatured alcohol, and which are at the same time remote from the source of supply of gasoline, alcohol may immediately compete with gasoline as a fuel for engines.

Seventeenth—If, as time goes on, kerosene and its distillates become scarcer and dearer by reason of exhaustion of natural deposits, the alcohol engine will become a stronger competitor, with a possibility that in time it may entirely supplant the kerosene and gasoline engines.

Eighteenth—By reason of its greater safety and its adaptability to the work alcohol should immediately supplant gasoline for use in boats.

Nineteenth—By reason of cleanliness in handling the fuel, increased safety in fuel storage, and less offensiveness in the exhaust, alcohol engines will, in part, displace gasoline engines for automobile work; but only when cost of fuel for operation is a subordinate consideration. In this field it is impossible to conveniently increase the compression, because of starting difficulties, so that the efficiency cannot be improved as conveniently as in other types of engines.

Twentieth—In most localities it is unlikely that alcohol power will be cheaper or as cheap as gasoline power for some time to come.

You will always find some special leaders in the advertising columns of this paper which our advertisers are constantly offering. Read the liners, especially, and the advertisements generally.

Harvest Time

Draws Near and Nearer

ARE YOU READY?

IF you have a crop of grain or grass growing, you naturally are beginning to think more and more about how you are going to reap the full benefit of the year's growth.

How you are going to turn what Mother Nature has given you, into the largest amount of golden dollars—

—How you may harvest your crop at the least expense, with the least delay and with no avoidable trouble.

Now is the time to make your decision—*not* just before you begin to cut your grain or hay.

You want to be sure that you are ready for harvest—that you have a harvesting machine not of the "may-be-so" kind, but of the "know-for-sure" kind—a machine that you can depend upon with all certainty and assurance.

You can't afford to try "to get along" with a wornout machine, for in all probability it will waste more time, more of the crop, and more of your nervous energy, than a new machine costs.

Neither can you afford to experiment with a machine. Let others do that if they want to and think they can afford it, but as for you, make up your mind to use *only* such machines as time and experience have proved to be successful and dependable.

For, after all, that is the only way in which you can arrive at a wise decision. All over the world during the past thirty to forty years, farmers have been using harvesting machines of many kinds and many types of construction.

Some they condemned beyond all hope, the first time they tried them.

Others they gave a second trial, only to find them wanting.

While to a few—a very few—they awarded the stamp and seal of their approval season after season and year after year.

Does not that mean something to *you?*

Do you know of any better guide than the thirty years' experience of *all* the grain and grass growers of the world?

Could you in a whole lifetime of investigation arrive at a surer decision than *all* the farmers of the country put together?

Of course not.

You know that in this day, the wide-awake farmer knows what he is about. If a majority of farmers favor a certain line of machines, it *must* be because that line has *proved* its value.

There can be no other reason.

And there *is* no other reason for the popularity and reputation of the six leading makes of harvesting machines now known as the International line:

Champion, McCormick, Osborne, Deering, Milwaukee, Plano.

Their popularity has increased from year to year because every year they prove to more and more farmers that they can be *depended upon* with certainty.

And today they are better than ever before in their history.

The International Harvester Company is able to employ, in the design and construction of each machine, every principle and every mechanical idea that more than thirty years of experience in this special line has demonstrated to be of value.

The International Harvester Company is able to command at all times, the very best materials that forest and mine produce—not only the lumber from its own forests and ores from its own mines, but by reason of its steady and increasing requirements and the desirability of its trade, it secures the pick and choice from hundreds of lumber camps, mines and mills.

The International Harvester Company very naturally attracts to its factories the most expert workmen, the most skilled mechanics; so that it has constantly at its command every facility for the improvement of its machines,

—every mechanical principle that experience has approved,
—the choicest materials,
—the most skilled workmen.

Do you wonder, then, that so many farmers all over the world refuse to use any other than these standard machines?

Do you think *you* can afford to begin harvest without first getting one of these machines?

See the International Dealer

and get a catalog of whichever machine you want.

If you don't know an International dealer, write nearest general agency for the name of the one nearest you.

Don't forget this other advantage. If your team runs away or an accident occurs, you can *always* get repairs for an International machine near at hand, and they *always fit.* A full stock of repair parts is carried at every agency.

Equal in importance with a perfect machine is perfect twine. The most perfect twine made may be had in Champion, McCormick, Osborne, Deering, Milwaukee and Plano, sisal, standard, manila and pure manila brands.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Nux Vomica.

Dear Cultivator: I clipped the following from the poultry department of a local paper:

"One tablespoonful of nux vomica to a quart of soft feed fed to chickens once a week will, after a few feedings, free them from mites, lice and all insects. Chickens should not be eaten for four or five days after feeding the nux vomica, but it does not affect the eggs."

Can you tell me whether it will hurt the hens or affect their laying qualities? Respectfully, N. E. M., Los Angeles.

It looks as if such an amount of poison as that would kill chicken lice and all the hens, too, and I should think if the fowls are too poisonous to be eaten after partaking of the food that it would be a most dangerous trial to make. When I read that I thought to myself, "How many hens will be killed by that?" I asked a doctor what he thought of this recipe. "More than enough to kill a dozen men," was his reply.

However, I met a homeopathic doctor in Hemet, who told me he had a homeopathic medicine which he fed to fowls to prevent their having lice. He promised to send me some (but it has not come,) for me to try. That may be homeopathic nux vomica and if he will send me some I will experiment with it, but not with the recipe you mention.—Mrs. A. B.

Scabby Potatoes.

Enclosed I send you a slice of potato showing scabby surface. Could you inform us what disease it may be, if any? It is seed shipped us from San Francisco and the farmers are suspicious of it. You would confer a great favor to myself and neighbors by giving the matter your careful attention and inform us what it may be and how to treat it and oblige an old-time subscriber.—Chas. R. B., Pismo.

The piece of potato you send is badly affected with scab. Soak the seed potatoes in a solution made of one ounce of corrosive sublimate dissolved in seven gallons of water. Leave the potatoes in the solution for one hour and a half. Scabby seed may be used with good results in this way.

Scaly Legs on Fowls.

I have got three or four roosters that got scales on the legs, they grow big; some people call them tumors and we don't know how to cure them. Please tell what causes that sickness. —C. V. B., Redlands.

Scaly legs is caused by the scale mite, a very minute insect, which you can see with a magnifying glass. It burrows under the scales and breeds there and it gets so bad that it "matterates" and Dr. Salmon says these insects will even burrow to the bone and the fowl will lose its toes and eventually its life. The cure is—take equal parts of coal oil, lard and sulphur mix together and rub well into the feet and shanks twice a week; at the end of a week wash in hot soap suds, and keep on repeating this till cured, which, if done thoroughly, will be in about two weeks. Or you can rub on mercurial ointment twice a week. The perches should be painted with some lice killer, as the mites travel along the perches and all the fowls will be affected if you are not careful.—Mrs. A. B.

Potato Blight.

C. M., Arroyo Grande, writes describing potato blight and what to do for same. The Cultivator has, several times during the past couple of years, urged the spraying of potatoes with Bordeaux mixture as a preventative, for it has been demonstrated that it pays in a larger yield of potatoes even though the blight is not present so as to be noticeable. The same spray is, of course, good for the trouble at all times and C. M. should spray all his potatoes at once. Those articles on the matter should have been clipped and saved by all growers of potatoes, even if only for their own use.

NORTHERN NEWS NOTES

Captain O. Cayer, Superintendent of Agriculture for the Spreckels Sugar Company at Salinas, says that the milking machines he installed some months ago are an unqualified success. He reports that the cows seem perfectly satisfied with the mechanical attachments to their lacteral fonts and keep up the flow as well as if not better than when they are milked by hand.

Last week John Ashurst brought down to Tres Pinos from his Vallecitos ranch, 28 head of steers to be shipped to San Francisco. The average weight of these "critters" was 1500 pounds, which was going some, considering the long drive. Four of the steers, however, weighed 2000 pounds each.

H. C. Peckham has sustained a loss of some twenty cherry trees at the old Peckham home place on the Salsipuedes near Watsonville. The ground about the roots received such a long continued soaking that the trees were practically drowned out and are dying.

The first cherries of the season raised on the Sacramento river were shipped to the California Fruit Distributing Company, Chicago. They were of the Knight's early black variety, were fine and large, and were raised on J. F. Elliott's farm in Courtland.

Many colonies of apricot scale parasites will be shipped from Sacramento into the fruit sections of the state and will be liberated in the orchards about the middle of next month. The parasities breed but once a year, and are active as soon as the flies are out.

The Corcoran people are not worrying about the lake. Measurements taken yesterday show that the town is fifteen feet four inches above the surface of the lake, and the nearest point of the lake is four and one-half miles from town.

The Hanford Sentinel has made inquiry recently among several orchardists, and they say the peach crop is coming along in fine shape, especially where the trees were properly sprayed with the Bordeaux misture.

The first box of cherries for the season was shipped last week from Vacaville to Philadelphia. These cherries are of the guingne variety and were grown by T. Lee Gates of Vacaville.

Despite all predictions to the contrary, from whatever source they may come, the fruit prospects of the great Anderson fruit section never looked better.

One field of barley at Corcoran, which stands as high as the fence, is estimated to promise a yield of 40 to 50 sacks to the acre.

Recently, the Salinas papers waxed proud over the weight of some grain-fed steers which tipped the scales at 2000 pounds each.

Mr. Hunter also has a thousand acres of alfalfa planted six weeks since, which is about three inches above the ground.

There is a general complaint from farmers of the Salinas valley of the scarcity of men and horses to do field work.

The Corcoran creamery, as stated by the Register Saturday, is now turning out 800 pounds of butter daily.

Mrs. Justgott Hermun—My new home has stained glass in all the windows. Mrs. Notyet Butsoon—Now that's too bad. Can't you find something that'll take it out?

When writing advertisers mention Cultivator

ANGORA GOATS ON THE FARM.

Many farmers who own land which, owing to its rough character, is scarcely fit for cultivation are looking into the merits of Angoras with a view to stocking their rocky, brush pastures, hoping to get good returns from the investment. All who contemplate taking up goat breeding would do well to invest in good grade Angoras rather than common ewes, even though the first cost is greater, because the fleece of the well-bred Angora, as well as her kid, will have a much greater value.

Half-breed goats will not shear marketable mohair, and not until a fifteen-sixteenths cross is reached does the fleece become really valuable. It will be readily seen, then, that valuable time is lost by grading up from common grades.

The difference in the price of mohair is considerable, running from 20 cents for low quality to 30, 35 and even 40 cents for some of fine quality. The long mohair is worth as follows: Twelve-inch, $1; 14-inch, $1.50; 16-inch, $2 and $3. The record price in this country was paid last spring for two bucks' fleeces that weighed 20 1-2 and 31 1-2 pounds, averaging from 12 to 23 inches in length. These were imported South African bucks, brought in by a Vermont breeder.

Probably the best way for anyone except the wealthy man, is to buy a few good does to start with, and in a short time he will have a flock of Angoras that will pay for all the trouble, and if he can keep them, the wether kids will pay for their keeping till they are three or four years old, when they can be fattened and sent to market. We keep mostly registered Angoras, although we have a few yearling and kid does that are not. But we have no brush land, but run them on the pasture fields to keep down brush and weeds. If you have a few Angoras your fences will not be the catch-all places they are on most farms, as the goats will not let thistles go to seed, but will eat off the blossoms when they head out.

While Angoras may be run on any kind of land, from brush to grass, at a profit, a few can be used on any farm to good advantage. A few people may have had some bad luck with them, but this was principally caused by bringing them from a southern climate and starving them on the way, so that they arrived in such a poor condition that they would not do well. If their habits and wants are studied and good judgment is used in their care, there is no reason why these beautiful creatures should not afford both profit and pleasure to their owner.

ANTHRAX.

According to reports Anthrax, which is perhaps the most dreaded of all diseases affecting the brute creation, is making its appearance early this season. Many of our readers no doubt know from actual experience how large the losses are when the disease makes its apearance in their neighborhood.

There is no known cure for Anthrax, but thanks to the discovery of that eminent French scientist, Louis Pasteur, we have a reliable preventive of the disease. In 1881 he discovered Anthrax Vaccine, which has been successfully used since that time in preventing Anthrax in all parts of the world.

The original and genuine Anthrax Vaccine can be obtained through Pasteur Vaccine Company, Ltd., of Paris and London, with New York and Chicago offices in this country, who are also glad to give our readers any information that they may desire on the subject. If interested, we would suggest that you write them, mentioning this paper.

COST OF IRRIGATION.

The above is the title of a valuable booklet just issued by the American Well Works, Aurora, Ill. The following are some of its suggestions: "Successful farming requires fertile soil, intelligent labor and water in abundance. The first two you have—we can provide you with water and all the necessary apparatus for irrigation, and the increased value of your crop will pay the bill the first season. Does this interest you?" The booklet showing figures about cost of irrigation and whether it is costing the reader too much will be supplied free to any of our readers who write them for it. Address, The American Well Works, Aurora, Ill.

Don't Feed

the little chicks anything for the first twenty-four hours. Then feed them dry.

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seeds, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keep it, and will not get it, send $3.35 for 100 lbs., freight prepaid by us to any point in California.

Are your fowls a little off—don't you want to tone them up?

West Coast Poultry Tonic

will do it sure. It is one of the greatest cures for ROUP and all kinds of colds.

Hen Fruit Pays—if you want more, feed

Egg-More

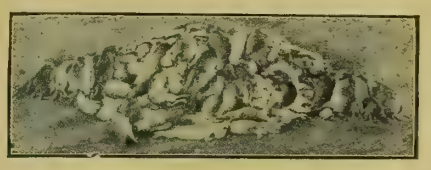
That highly nitrogenous poultry food, rich in protein, to keep the poultry in good health, and enable the hens to convert the surplus aliment into eggs. Just the right addition to a good grain ration.

West Coast Lice Killer and Killamite (powder)

are most effective pest destroyers. Nearly all the diseases of poultry may be attributed to lice and mites. Don't let them get the best of you. Get the best of them. And did you know that Killamite is just as good for killing plant insects without harm to the plant. Testimonials of public gardeners and others. Try it on your roses. 50c sifting cans by mail if your dealer won't get it for you.

West Coast Poultry Foods and Remedies

are the best made and, quality considered, the cheapest. If your dealer doesn't sell them, send to us. Booklet free. Send us names of 12 persons keeping poultry and we will send you free "The Poultry Manual" by those high authorities F. L. Sewell and Ida E. Tilson, profusely illustrated.



This is a photo of 201 Gophers killed in one day on a 10-acre field with one bottle of

BILLE'S GOPHER POISON

Not one of the ordinary poisons, but in a class by itself. Endorsed by Agricultural colleges and Experiment Stations. Has had greatest success in the Middle West. The secret being that it is most attractive to gophers, squirrels, etc., and sure death to them. It gives the grain a glossy coating, retaining the poison for weeks. Hundreds also die in their holes by eating it there. We have bought the patent right for this section and are selling at the eastern price, lower than the ingredients can be bought at a drug store. Money refunded if not as represented—so printed on the bottle. If your dealer does not keep it sent $2.50 for two bottles, express prepaid by us—not less than two bottles.

Confident that a trial will prove beyond question that the best condition powder made is

West Coast Stock Food

We will send to new customers one 25-lb.

$3.00 PAIL FOR $2.00

or one 50-lb. $5.75 double sacks for $3.50, and will prepay the freight to any point west of the Rockies. Not more than 50 lbs. to each one, and we reserve the right to withdraw this offer without further notice. No cheap premiums, no gaudily colored pictures, but a legitimate business offer to induce a trial, hoping to add many steady customers. We are charging up the difference to our advertising account, feeling sure that a trial of the goods is the very best advertising.

No strings to this offer. Just send us your name, the freight station to whch you want the goods shipped, mention this paper, and we will do the rest. Send money order or check with your order, and if every thing is not exactly as represented your money will be refunded. The First National Bank of this city, or Bradstreet's Agency, or any leading firm, can inform you as to our reliability. WEST COAST STOCK FOOD has for many years been a standard condition powder in this section. See our full page adv. in the March 7th and 28th issues of this paper or send for circular with testimonials.

818 San Fernando St. (through to Alameda) Los Angeles, Cal.

The natural asphalt in Genasco Ready Roofing is like sap in a tree.

Keeps it alive, keeps off the rotting, drying, melting, cracking, destructive influences of weather.

Nothing else does. You know how shingles warp and rot, tin rusts, slate breaks, coal-tar dries out and cracks.

The Trinidad Lake asphalt in Genasco is centuries old and is still water-proof. It will last as long as you need it.

Wide-awake dealers everywhere sell it—smooth or mineral surface.

Household Department

LITTLE BOY BLUE.

Under the haystack, little Boy Blue
Sleeps with his head on his arm,
While voices of men and voices of maids
Are calling him over the farm.

Sheep in the meadows are running wild
Where a poisonous herbage grows,
Leaving white turfs of downy fleece
On the thorns of the sweet, wild rose.

Out in the fields where the silken corn
Its plumed head nods and bows,
Where the golden pumpkins ripen below,
Trample the white-faced cows.

But no loud blast on the shining horn
Calls back the straying sheep,
And the cows may wander in hay or corn,
While their keeper lies asleep.

His roguish eyes are tightly shut,
His dimples are all at rest;
The chubby hand tucked under his head,
By one rosy cheek is pressed.

Waken him! No! Let down the bars
And gather the truant sheep,
Open the barn-yard and drive in the cows,
But let the little boy sleep.

For year after year we can shear the fleece,
And corn can always be sown;
But the sleep that visits little Boy Blue
Will not come when the years have flown.

—Abby Sage Richardson.

WOMAN'S DIPLOMACY.

PROVIDENCE, who manages all things wisely and economically, wastes no talents on man for the management of woman. The wisdom of this course is that man needs no such talent until after marriage, and after marriage he has a wife to manage other women for him. The economy consists in the fact that men shall marry. A single man never appreciates the sensitiveness of the opposite sex. Woman hides her wounds, and man often stamps through her feelings with seven league boots.

An incident that occurred to me after my marriage taught me this, and since then I have invariably left the settlemen of my differences with other women to my wife. I had passed middle life before marrying. I had met ladies, as other bachelors meet them, socially, but my club was my home, and I was never thrown into intimate association with any woman. But I considered myself sufficiently mild mannered and deferential to the softer sex for all ordinary social purposes. What wounds I had inflicted I did not know, nor was I conscious of having inflicted any.

The honeymoon over, my wife took me in training, and it soon became apparent that I needed a great deal of it. However, in about a year I supposed I was thoroughly educated. One day my wife informed me that her dearest friend, whom she had not seen since we had been married, was coming to visit her, and she was specially anxious that I should make a good impression. I resolved to be on my guard and put on my most affable and deferential manner.

The first evening of Miss Bland's arrival my wife, my sister and our guest sat down to a game of whist. I was of course assigned to play with Miss Bland. I got on swimmingly. I saw that my partner knew little of the game, and it gave me an opportunity to show my wife that I could pass her friend's mistakes without the slightest reference to them. I would probably have gone through the evening without trespassing on my partner's feelings had not she made a misplay that gave me an opportunity, as I thought, to make a brilliant strike in soothing her.

I had a fine long suit, all of which I could make if I could draw my opponents' trumps; but, having only four trumps myself, all depended upon my partner husbanding hers. My wife led a small spade, and I, desiring to get the lead, put on the king. When my partner played, the trick was mine. She trumped it. I winced, but said nothing. My partner's error gave our opponents the odd trick.

"I shouldn't have trumped your trick, should I?" said Miss Bland, reddening.

My wife explained to her that to trump one's partner's trick was not considered always the best course, but that in this case it didn't matter since we were playing for fun.

I didn't see the fun in playing that way, but refrained from comment.

"Now I think of it," said Miss Bland, much mortified, "somebody told me once that to trump one's partner's trick was the worst mistake a player can make."

My wife looked at me appealingly to say something to make my partner feel easier, and it was then I tried to soothe her.

"You only trumped my king. There is a worse thing than that." I said softly.

"What is it?" asked Miss Bland.

To trump your partner's ace.'

Miss Bland cast a quick glance at me, and I cast a glance at my wife, expecting to see approval in her face. I saw a frown.

There was an ominous tremor on Miss Bland's lip, and presently she arose, left the table and went upstairs.

"Now you've done it," said my wife as she left the room to follow her friend.

I walked up and down the floor cursing myself for a fool and wondering if my wife would be able to explain matters and get me out of the scrape. I also wondered how she would manage the diplomatic task. Of course she would tell Miss Bland—what else could she tell her?—that I had intended my remark to make her blunder seem less a blunder. But had I solely so intended it? Women are quick to see a slight, and perhaps Miss Bland might have detected a trace of sarcasm in my voice. "Thank heaven," I muttered, "it's woman against woman. I'm sure the more I excused myself the worse I would make the matter."

My wife returned, but without her friend.

"Well?" I asked eagerly.

"She's coming down presently, after she's got rid of the appearance of tears."

"Tears?"

"Of course. Do you suppose her feelings are sheet iron?" Then, seeing the pain she was inflicting on me, she added, "It's all right now."

"Did you tell her I intended"—

"Nonsense! I told her nothing of your intentions."

"What did you tell her?"

"Why, I told her that you had been a bachelor all your life, had lived at clubs and all that and hadn't been used to playing cards with women—in short that"—

"I didn't know any better."

"Yes."

"And it made her feel all right?"

"Yes."

"My love," I exclaimed folding her in an embrace, "you're a brick. You can beat me at diplomacy every time."

Miss Bland came down, and the game proceeded. She and I became fast friends.—Alexander Ely.

A SUBSTITUTE FOR GLUE.

If you have no glue handy, and you want to stick something, try this. Take a small piece of cold boiled potato and rub it down with your finger on a piece of paper for about five minutes. It will then be of the right consistence, and will stick as well as the strongest glue.

SEEDED RAISINS.

Seeded raisins and citron chop much easier if boiling water is poured over them and they are allowed to stand a few minutes, when it should be drained off.

The following little anecdote told recently carries a great meaning:

"Mary, come out, the violets are in bloom."

"No, I cannot, I am housecleaning."

"Dirt will keep, but violets won't."

She went.

The most important thing in the world to me is a lamp-chimney.

I have been for years and years making the best, and always trying to make them better. I put MACBETH on them and no one ever disputes my claim.

The Index explains how to get a MACBETH chimney to fit every lamp, and how to care for lamps. Sent free to everyone asking for it.

Address, MACBETH, Pittsburgh.

DECORATION IN THE HOME.

"Decoration in the Farm House," besides suggesting principles in home decoration, emphasizes the desirability of simplicity. We gather too much about us; it collects in the cupboards and on the shelves; it has to be dusted; it occupies a place where space would be more expressive; it has become meaningless in our lives; it seems too good to throw away but it is really doing more harm than good; it troubles us as any other clutter will. Our tastes have changed since certain ornamentation was placed in our parlors. We may have thought it a desirable acquisition at the time and no doubt it did us good then. If it does not do us good now, it has served its usefulness.

Beauty is in the mind of the observer and we have a right to change our minds. Our larger fault is in clinging to old sentiments. We need to throw away many of them and to get new ones. Our lives need this rejuvenation.

The question arises as to what to do with the mats, the vases, the mottoes, the picture cards, the poorly framed pictures, the lambrequins and whatnots. A good motto is to keep that which is uplifting as long as it remains so. Then if it is likely to be helpful in the life of some other person, it may be passed on. If it is not calculated to serve that use, it should help to make a bonfire.

We may not understand the principles of art, and yet be possessed of artistic temperament or capable of artistic training. We may hold the erroneous idea that to be artistic one must express it by painting a picture. Everyone may express an artistic temperament either in dress, in house furnishings, or even in the arrangement of flowers in a vase. This is the adaptation of the artistic sense to life itself, which is the best aim in education.

One simple and effective standard is nature itself. A pot of flowers, a vase of flowers, effectively placed is worth all of the questionable ornament which can be supplied. Life has zest just in the contemplation of these simple forms of art.

HUSBANDS WHO NEVER PRAISE.

Apparently there are some men in the world who would not be likely to live long if by any possibility they should be betrayed into praising their wives. The man of this description is a self-sufficient creature, who evidently believes that creation was instituted for his benefit. He is a little surprised and a good deal annoyed that things were not arranged more to his liking, but he tolerates the arrangement, not because he approves of it, but because he cannot help it.

The wife of this man is a woman whom no old maid would envy. And no old maid should every marry this man when his first wife is worn out and laid in the grave; if she does she will regret it to her latest day—that is, unless she has backbone enough to put the man where he belongs and keep him there. And it is never pleasant to any true-hearted woman to feel that she has to master her husband in order to live comfortably with him. The man who never praises his wife will find fault with everything on every possible occasion. It is the easiest thing in the world to find fault—easier than the proverbial sliding down hill. It gets to be a habit with some men, and they are hardly conscious when they are exercising it.

Why cannot a man show his wife that he appreciates her efforts to please him? Why cannot he praise the pudding of his wife as well as the pudding of her neighbor, Mrs. Jones? Why cannot he speak kindly of her mince-pie, and charitably of her sponge cake? Why cannot he say that the bonnet is becoming to the face of the woman who loves him? Kind words make his wife happy, and no decent man ought to withhold them.—McCall's Magazine

TO KEEP OUT FLIES.

Keep a box each of blooming mignonette and geraniums in your open windows to prevent the entrance of those nated intruders known as flies. A few drops of oil of bay leaves kept in a tiny dish near the window will have the same effect, it is said.

Domestic Swiss	22
Imported Swiss	30

Eggs and Poultry

Receipts of eggs yesterday as shown this morning by the reports of the Los Angeles Produce Exchange were less than for the two days previous and the egg committee put the official selling price back to the former quotations—20 cents. There was active trading in eggs today and an effort was made to influence the market by selling freely during session. As a result 40 cases of eggs changed hands at a price which it seemed would prevent the committee from raising the selling price, but the eggs were sold by only one or two dealers, while buying at the price was general.

Eggs local, per doz	20
Northern Candled	19
Fresh Eastern	18

The following are average prices which dealers pay to producers for live weight:

Value of Irrigating Water in California

LESS than a score of years ago water for irrigation was procured in California only by diversion from streams where the task was extremely simple of solution.

As the value and possibilities of irrigation gradually dawned upon our rural residents, more labor and money was cheerfully expended until continued demonstrations forced a rise in land values, because of the immense profits of fruit growing through irrigation, until now it is a question of where only—the outlay of dollars being scarcely heeded, if the desired ends be attained.

Now vast ditch lines and irrigation flumes are carried around the mountains or in tunnels made through them, for many, many miles, and no cost is considered too great if the life-giving fluid can be brought to the parched earth, where our wondrous western climate rapidly transforms our otherwise arid wastes into fields and gardens of marvelous beauty and unequaled profit. Many of these waterways, like one above pictured, are marvels of engineering, winding around the hills like huge serpents of mythologic lore and the waters they carry really work wonders as seemingly impossible as these weird, wild tales so familiar to childhood's impressionable years.

Coulson's Mixed Foods

Must Be Used From The Start

Waiting for meal of Special Dry Chick Food

If you want to get plenty of eggs in winter, you must start your plans by raising lots of chicks in the Spring.

RAISE THEM ON

Coulson's Special DRY CHICK FOOD

Planning a Profitable Cropping System

A Careful Study of Experiments in a Too Much Neglected Line and One Most Necessary for the Best Financial Returns

By W. J. SPILLMAN, Agent in Charge

THERE are two principal reasons why work of this kind is undertaken. In the first place, very few farms have any definite cropping system, and it is comparatively easy to plan a system that will meet the requirements of the case and increase the farmer's income.

We are thus able to render material service to a considerable number of farmers, whose farms in consequence become centers of local interest and serve as object lessons to the community. In the second place, the number of farms on which the full possibilities of a given type of farming are realized is exceedingly small; so small, in fact, that it is necessary to increase the number very materially before many important problems relating to farm management can be solved.

To Illustrate: On the farm of Mr. W. H. Rowe, described in Farmers' Bulletin No. 272, the possibilities of a given system of managing swine with a particular cropping system have been worked out. One litter of pigs a year is produced. These are pastured on clover in summer and fed sufficient grain to bring them to a weight of from 100 to 125 pounds by the end of the pasture season. In winter they are fed grain and soy bean hay. The next summer they return to the clover pasture, while the feeding of grain continues. About the 1st of August they are sold, weighing from 325 to 350 pounds each. This system utilizes the full possibilities of the clover pasture. The extra hogs during early summer consume the abundant growth of clover at that season, while the smaller number later find just about the amount of pasture they can utilize.

With this system the farmer is able to sell an average of six large hogs a year for each acre in clover on the farm. This farm is in the North, where winter pasture is not available. The owner knew just what acreage of each crop to grow, and he knew approximately the quantity of grain and mill feed he would need during the year. This is the only instance thus far found in which a farm devoted to hog raising had its problems so fully worked out.

Suppose, now, a hog farm is located far enough south to make winter pasture available, and that it is desired to produce 200-pound hogs. Fall litters of pigs may be given pasture and grain during winter and early summer, the grain being so apportioned as to cause the hogs to reach the desired weight, say, by the 1st of July. Spring litters may be given pasture and grain till autumn, and then penned and forced rapidly to a weight of 200 pounds.

In such a system, on a farm of a given size, what acreage of winter pasture and of summer pasture should be provided? What pasture crops should be used? How much grain should be feed? These are questions that can only be answered by experience. We are able to make estimates that will serve as approximate answers, but the experience of a considerable number of farms is necessary before these estimates can be relied on.

There are similar questions that need to be worked out in connection with nearly every type of farming for every section of the United States. One of the most important reasons why detailed plans are drawn in this office for individual farms is, to enable us to find valuable material for the study of the possibilities of the various types of farming. Among a large number of plans furnished, some will result in the development of farms to their full possibilities. Every such farm is an object lesson of great value. A large number of such farms would furnish data for generalizations of inestimable value.

The number of distinct types of farming is large, and most farms combine two or more of these types. Even farms of exactly the same type—as, for instance, dairy farms that grow only roughage and buy all the concentrates—may and do have widely different cropping systems. This is true even on contiguous farms of the same type. This field of research is therefore a wide one. It relates in a most vital way to the development of the agricultural resources of the country. If properly pursued it can not fail to result in the accumulation of a vast number of important facts and principles which can be put into pedagogical form and thus become an important subject of instruction in schools.

In attempting to plan a cropping system to fit exactly the needs of a farm, the objection may be raised that this is impossible because of the great seasonal variation in yields. This objection overlooks the fact that every farmer in the United States is actually compelled to make such plans every year, whether they are feasible or not. There can be no two answers to the question whether we shall attempt to aid the farmer in this the most important work he has to do. If agricultural science is of any value at all it must aid the farmer in planning his work.

With sufficient study, the ordinary fluctuations in yields become known quantities, and allowances can be made for them. When a farm is heavily stocked, it will occasionally occur that feed will run short. In such cases the only resource is to buy, unless the farmer is willing to dispense with a portion of his stock It should be remembered that when a farmer is buying feed he is also buying fertility. One of the most successful farmers in this country says: "I usually keep enough stock to eat all I raise, and I usually take the chance of keeping a little more; for it does the farm no harm to buy a little feed if it is needed."

The plan selected to illustrate the methods used in arranging a cropping system to fit definite conditions is one recently drawn for a farm in northern Illinois. The manager had already determined approximately the possibilities of this farm under the particular type of farming he desired to follow. The number of conditions to be met was unusually large. It was desired to keep about 25 cows, 5 to 15 head of horses (some of these to be kept for city owners), 50 to 60 hogs, and 100 hens. It was desired that a farmstead be reserved in the northwest corner of the arable portion.

It was preferred that all the stock should be provided with pasture. At the outset it was plain that ordinary permanent pastures for all this stock would occupy too much land. It was therefore decided to provide more productive temporary pastures. The condition of the land justified the assumption of the following yields: Silage, 9 tons; hay, 2 tons; soiling corn, 7 tons. It was assumed that by feeding 5 pounds of hay or 20 pounds of soiling corn per head daily, the pasture could be made to carry 1 cow per acre.

The Rotations Adopted.

A careful consideration of the conditions specified and of the many different possible rotations led to the adoption of one three-year rotation as follows: First year, 7 acres of corn and 18 acres of peas and oats; second year, timothy and clover; third year, timothy and clover.

This rotation requires that timothy and clover be sown in the 7 acres of corn at the last cultivation, a common practice in New England and a successful practice on several farms in Iowa, Missouri, and other Western States. Timothy and clover are also to be sown either with peas and oats, or immediately after the latter are harvested for hay. The third year of this rotation furnishes the necessary pasture for the cows; the second year furnishes the required 10 acres of pasture for the horses and 15 acres of hay. This will require a temporary fence, which, however, is entirely feasible.

In case the seeding of grass fails, rye may be sown after the corn in the fall, to be followed by soy beans for hay the next summer. If the seeding of grass after the peas and oats fails, winter wheat should be sown on the land needed for horse pasture. This will furnish good pasture throughout the summer, as the wheat will not stool until late in the fall or early the next spring. The remainder of the pea and oat land may very properly be planted to sorghum for hay. The next year the whole 25 acres may be sown in winter wheat in the spring, to be used by the cows for pasture during the summer.

To secure the five acres of clover for the hogs, in a rotation in which the remaining crops are useful, the following three-year rotation was arranged: First year, corn, in which clover is sown at the last cultivation; second year, clover; third year, peas and oats for hay, followed by rape sown in midsummer.

This rotation permits more rape to be grown than is strictly needed, but the extra quantity can be utilized by the pigs and calves.

If the seeding of clover in the corn fails, sow winter wheat in half of it in the autumn. Pasture this wheat down the next spring, and follow it by sorghum for hog pasture, turning the hogs in on the sorghum when it is about 18 inches high. The other half of the land should be planted to winter wheat in the spring. This will furnish good pasture for hogs throughout the summer.

These two rotations occupy 90 acres of land, and furnish 12 acres of corn, 38 acres of hay, 5 acres of rape, and all the pasture needed. There are still needed 5 acres of corn and 7 acres of hay. Reserving 3 acres for the farmstead, 10 acres on which to grow these crops are left. The evident solution of this problem lies in a two-field rotation of corn, 5 acres, followed by a double crop of hay the next year.

Deciduous Fruit Culture

By J. W. MILLS

POOR NUTS.

ASIDE from the fungus diseases that attack California nuts, there is perhaps nothing that makes a poor grade of nuts as lack of water at a certain period of development.

This is particularly true of the almond. A shortage of water will not only prevent the present crop of nuts from making full and plump kernels, but it shortens the coming crop, barring accidents which might also shorten the crop. It has been our observation that when almond trees were sufficiently supplied with moisture to allow them to form considerable new growth and set a good many buds on the inside spurs while the trees carried and matured a crop, the trees would bloom well and set a crop the following year. It is simply a question of keeping the trees growing.

We have noticed that when the trees stop growing before the nuts ripen, the present crop is not only injured, but the bud development is so retarded that no crop for the following year can be possible. The year that follows with little or no crop is free to make a good growth because there is no crop to mature and as a result there is a year of light and heavy crops or a heavy crop followed by no crop at all.

It is commonly thought, or used to be by many, that the almond and olive would flourish and be prolific on land so dry that other fruit trees would not mature crops on them. This idea is fast being corrected. It has been noticed that the almond in particular bears better year in and year out on moist land that is more subjest to frosts, than dry land which is more favorably situated in respect to frosts. This demonstrates the great importance of irrigation when nut trees are planted on land not naturally moist. The California walnut, the pecan and in fact all nut trees are naturally deep-rooted. This would teach us that if they do require an abundance of moisture, irrigations must be long and thorough to do any good. The water must go down to get to the trees.

Poor land will not make good, plump nuts. They are very nutricious fruits and they must get their richness principally from the soil, and if the soil is poor, the nuts will be poor. The larger percentage of the mineral elements that enter nuts is used up by the husks. If these are returned to the soil the supply will not be so quickly exhausted. Eight to ten pounds of a well balanced fertilizer per tree for a full bearing orchard is not a heavy dose.

NEW GRAPES.

Within the last few years new varieties of grapes have been introduced that have proven favorites in the various parts of the country. Still there are so many varieties and they grade into one another so gradually that really there is not so great an acquisition in any of them as is generally supposed.

The Pierce grape, for instance, is a very fine grape in its class, but there are many varieties that are equal if not better. The Millennial is another new grape brought out quite recently with favorable reports. It is not a new grape, having been discovered in Hungary in 1887 and introduced into California two years later, but it was not widely distributed until recent years. It is being grown on trial in the Imperial valley as a shipper for the early market.

McPike is another new grape for which must be claimed. At this time nothing has excelled the Malaga in the desert sections for an early shipper. It produces well, it is attractive and has a good flavor. Perhaps more of this variety will be grown in that section than any other kind, though some others are very promising, especially Purple Damascus.

PEAR BLIGHT.

While discouraging reports are heard about the pear blight which has wiped out so many orchards in this state and which will destroy many more, there is one grower in the Sacramento valley who has been successful to a high degree. He has considerable acreage in the Feather River bottoms in Yuba county. Mr. Howard Reed has this orchard and has treated it after the directions of the pear blight investigators who were sent out from Washington. He was rewarded last season with a fine crop of fruit and his trees seemed to be in a healthy condition. If these conditions prevail with him this season, it will demonstrate that the pear blight can be controlled.

FARM AND ORCHARD WORK.

In our California climate the years roll round so quickly that one season seems to be merged into another. We have no distinct dividing line as they have in most civilized countries, and no weary waiting for the season to open to resume interrupted operations. Even our rains are oftimes a relief as affording a much needed rest.

This has its advantages, but it also has its drawbacks. To the young man ambitious in making a start it enables much to be accomplished, as the season for every kind of work can be extended over a much greater period, with but few interruptions from inclement weather. For instance, our planting season for deciduous trees, including preparation of the ground, easily extends over four months, or say from the first of November to the end of March, and may sometimes be successfully done in April. While again, orange tree planting may be done any time during the active growing season. In like manner, farming operations can be carried on successfully over a greater portion of the year. The advantage is with the ambitious, struggling beginner. The drawback is that it, in a manner, deprives us of all leisure as the climate gives such a bouyant feeling that too much is apt to be attempted.

April ushers in the growing season, and is apt to crowd a great deal of work into a short time, unless the orchardist has been beforehanded and has not set himself too much of a task.

When the ground has been run together and packed hard by the copious rains of the winter, if it has been by any means neglected until April, it will be hard to get it into a desirable state of cultivation, so as to retain the moisture beneath the surface. It will be found that the evaporation from all sun-baked surfaces is much greater than where it is covered by a coating of weeds or other vegetation. Unless there should come a more generous rain than can usually be expected in April, but little can be done except to run furrows for irrigation where water is to be had, and it is presumed that no prudent orchardist would be so neglectful as to miss the opportunity of conserving the moisture by occasional cultivation.

The writer has had as good success in previous years where grass and other vegetation was left to grow until nearly mature and the surface moisture mostly gone—then, if not previously done, furrow, irrigate, then plow thoroughly but not too deep, in the orchard, and bury everything in the shape of vegetation. If plowed at the right time the ground will turn up very mellow and will retain its moisture for a very long time afterwards. This looks slovenly during the winter, where the aim of many of our orchardists seems to be to keep everything in the line of vegetation from sprouting. But the writer makes the prediction that the scarcity of coarse vegetable fertilizer will compel such methods as this to be pursued in order to keep the proper amount of humus in the soil, which cannot be supplied by any commercial fertilizer, and which cannot be properly utilized unless the ground has a proper quantity of humus.

Deciduous trees can, in an emergency, be planted as late as April, provided the trees have been properly heeled in and have started out to grow in a vigorous and healthy manner, but great care must be exercised to keep the little rootlets that have started from dying out. The roots should be puddled and kept moist from the time they are taken from the nursery until planted. Immediately after planting, irrigation or watering by hand from barrels on a sled or wagon is necessary. In this way, for a starter in a family orchard, a year's growth may be saved, which is worth a good deal to a new settler on vacant lands.

FERTILIZER LORE.

I notice an article in your issue of April 4 wherein the writer says: "One may rest assured that he pays too much for the brand of low value, instead of too little for the brand of higher value."

I judge from this somewhat ambiguous remark that the average fertilizer manufacturer, according to the writer's notion, is overcharging for his goods. This is not by any means the case. Fertilizers, taking into account the cost of labor, transportation of materials, etc., are as cheap here as it is possible to make them and make them good, and how good the average fertilizers are that are sold here and their value to a cent, any one can see for the expense of a one-cent postal to Berkeley for the semi-annual bulletin. By the way, I might mention, en passant, that the fertilizer manufacturers of Southern California, and especially the A.C.W., were instrumental in obtaining the fertilizer law, and the publishing of the bulletin of fertilizer values. I say the manufacturers did this of their own volition; furthermore, they have helped to increase the citrus and other crops many thousands of carloads by good, practical work done in the field, and that various firms have certain formulas that are adapted to certain conditions, no practical man can deny, experiment stations notwithstanding.

It was the custom in the past for some experimental stations to discourage the use of commercial fertilizers, possibly with the best intentions, but the grower who does not use commercial fertilizer is the loser now; and another fact is that the fertilizer man who takes an interest in and is making a success of his business knows more the requirements of a grove than the grower, for the reason that the fertilizer man sees one hundred groves and one hundred different conditions where the average grower's observations are much less limited.

Complete fertilizers cannot be purchased on the unit basis, for the simple reason that a fertilizer of a higher unit value does not always give the highest agricultural value in the field. Many times a grower could afford to give more money for the lower unit value, because the composition and source of plant food suits his particular crop and soil.

Remember this as an infallible rule, that the commercial or unit value does not always designate the agricultural value of a brand of fertilizer.

The article advises all growers to buy on the unit basis, but then says: "It is not intended to discuss here what materials are best suited for various crops under various conditions, but to suggest to the buyer of fertilizer that they should know what they want and then go to the fertilizer dealer to supply their wants." Thus admitting what I contend, that certain mixtures and combinations are better than others under certain conditions.

The article also says the brand or name for what the manufacturers think is best suited for the crop for which the brand is intended, or else it stands for what the manufacturers wish the farmer to think is best suited for his crop in order that the manufacturer may dispose of, at best advantage to himself, fertilizing materials on which he has a corner, or which he can procure on more favorable terms than others. This is casting a direct slur on the integrity of the fertilizer manufacturers, who with no help from the stations and in spite of such articles as referred to here, flourish. Why? Because their business is to do the best they can to help the grower to get crops. Make him crops, and you sell him fertilizer; show no results, and you don't. That's all.—H. E. C.

TUSSOCK MOTH POISONING.

The fact that the tussock caterpillar is not readily poisoned by arsenicals has been alluded to in the opening paragraphs of this bulletin. It was hoped, however, that some method of application might be discovered which would prove successful as a means of control.

Some laboratory experiments were conducted in 1905 with this end in view, and it was found that the newly hatched larvae were more readily poisoned than the more mature insects.

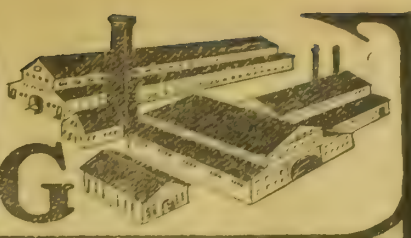
Arsenate of lead was the material experimented with. When the foliage was thoroughly covered with this insecticide applied at a dilution of three to six pounds to fifty gallons of water (the wet weight of the material as taken from the keg,) and newly hatched larvae were placed upon it, the majority of them died from arsenical poisoning; but even then some survived and only succumbed after prolonged exposure to thoroughly poisoned leaves. Slightly older insects were found to be extremely resistant; some survived four weeks, when their only food was leaves literally whitewashed with arsenate of lead. These larvae ate but little, and doubtless died from the combined effects of starvation and arsenical poisoning.

It was then evident that even early spraying with heavy doses of arsenate of lead might not prove successful, for, added to the resistance of the insects would be the difficulty of keeping the rapidly expanding foliage covered with poison. The feeding habits of the young caterpillar were also against success, as they worked largely on the buds and blossom clusters, which were very difficult to cover with spray. Also, the frequent rains that occur in the early spring tend to render spraying ineffective; and, last, but not the least important, the prolonged period of hatching, which covers nearly four months, is against the success of such a spraying campaign.

Notwithstanding all the apparent difficulties, some early spraying experiments were undertaken this spring, notably in orchards of Messrs M. B. Tuttle and R. W. Eaton. Spraying began in the Tuttle orchard on March 8, and continued, owing to delays caused by the rain, for about three weeks. Arsenate of lead was used at the rate of three pounds to fifty gallons of water, and the trees were thoroughly sprayed. The caterpillars were hatching abundantly at this time, and there were also a great number of larvae which had passed the first and even the second molt.

Spraying in the Eaton orchard was not commenced until March 29. Here 5-5-50 Bordeaux was used, with three pounds of Swift's arsenate of lead to fifty gallons of the mixture. The trees were still in blossom at this date and the tussock-moth larvae were yet hatching abundantly, but many of them were in more advanced stages than when spraying was commenced in the Tuttle orchard. The spray was thoroughly applied in each case and many young larvae were killed, but the treatment did not obviate the necessity of treating the trees several times later, in order to prevent their defoliation, and, in spite of all efforts, the fruit was badly damaged.

CONGO ROOFING



Doesn't harden in the sun, or crack in the cold.

Doesn't shrink at the seams. Always waterproof—always tight.

Light in weight; low in price; no imperfect rolls. Absolute satisfaction always.

Congo Roofing makes a fire-resisting, durable roof. Any one can lay it.

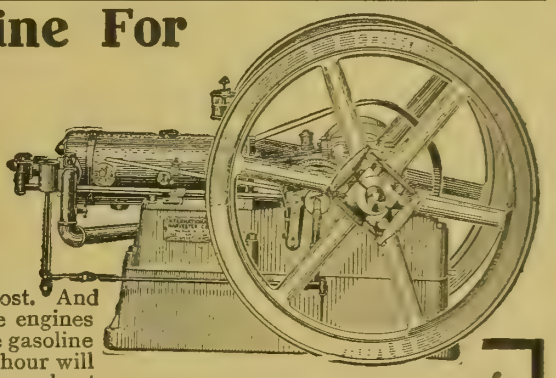
LITTLE GIANT working

Get an Easily-Operated Engine For

IRRIGATION PUMPING



WHEN you buy an engine for irrigation pumping you don't want to get one that will require an engineer to run. What you want is an engine that will practically run itself for hours at a time. One that is sure and safe and steady, one that is simple in construction, and easily understood and operated.

I. H. C. Gasoline Engines are that kind, and for that reason are especially adapted to pumping for irrigation. A small boy can look after an I. H. C. Engine, and run it as successfully and economically as anyone. Look it over once or twice is all that's necessary in a day's run.

Now, what else do you want in an engine for irrigation pumping?

Economy—To be sure, you want an engine that will pump the largest amount of water at a small cost. And here again I. H. C. gasoline engines fill the bill. Ordinary stove gasoline is the fuel, and the cost per hour will be about 1½c per horse power—about 45c a day for a three-horse power engine working 10 hours. That's cheap enough isn't it? And convenient. You can buy gasoline by the barrel, and always have plenty of fuel on hand.

Durability—Because I. H. C. engines are simple and strong in construction, they are durable, too. There's nothing much about them that can wear out. Repairs are small and inexpensive; parts can always be readily obtained, and you can replace them yourself.

Ease of Operation, Economy, Durability—these are three good points that help give I. H. C. gasoline engines a superiority over others.

If you are now using any other power, or if you are planning to pump for irrigation this year, go to our local agent and examine these famous engines. They are made in various styles (Vertical and Horizontal, Stationary and Portable) and in sizes ranging from 2 to 20-horse power. During the seasons when not in use for pumping they can be made to serve in a hundred other ways.

BUTTER MAKING.

IN the Bible in the triumphal song of Deborah the value of butter making is mentioned, for when Sisera asked Jael for water she brought him a cup of milk and a lordly dish of butter. Then after gaining his confidence by her generosity drove the fatal nail through his head. A cup of cold water is spoken of as the least of simple kindnesses that one can give to their fellow man. A cup of milk in many countries is a high mark of regard, while a dish of butter is recognized as a dish to honor a king. Water—Milk—Butter. The relation is still more intimate than we think. Water, first. I feel you are all smiling to think of water in the milk question. The watering of milk by direct turning the water into the milk is almost a thing of the past. The only way left is to water the milk through the cow. Prof. Cook used to give his cow a gallon or two of salted bran tea to help out the milk flow.

Capital in Dairying.

In late years the money made in dairying has attracted the capitalist until the small dairymen are being swept aside rapidly. The modern sanitary dairy requires a large outfit of tools and appliances. The old time dairy outfit consisted of a few cows of no breed, a corral to milk in, a few pails and cans, a strainer and a milking stool to sit on or to comb the cow into submission as was needed. This was a full outfit. Now we have cows of a dairy breed, a sanitary barn, a cooling apparatus, covered milk pails, brushes for the cows and a steam boiler for sterilization of the pails, cans and other utensils. Other wrinkles that the local health officer thinks should be used; these change with each administration.

Water.

The water used in washing milk pails and cans has been known to carry pathogenic bacteria with it, giving rise to typhoid and scarlet fever. This, however, is aside from our subject today. The bacteria in the water we wish to talk about is that which gives rise to taints in the butter, the water the butter is washed with may ruin it for eating purposes though it may not be injurious to the health of the consumer. The large creameries, when the cream in the vat becomes tainted, pasteurize it and use a commercial starter for a few times and escape some of the more serious troubles that the small butter maker must meet. They can make a butter that will hold its own until sold at least.

Export Butter.

The butter made from ripened cream is the popular butter in the United States. When the creamery men were newer in the business milk was often received that should not have been taken in at the creamery doors. From it good butter could not be made. After these troubles passed the time came when butter fell in price until the Government concluded to help by making a series of experiments in exporting butter to other countries. A number of shipments were made to different parts of the world. It was then discovered that some butters kept much better than others. That the butter was good at first was shown in that none that scored less than 95 was sent out. It all went in cold storage and all had nearly the same treatment. The cause was discovered to be in the growth of bacteria that produced the disagreeable flavors.

Experiments.

Bacteria was then purposely introduced into the cream and also into the water to wash the butter.

In one lot too much butter milk was left, in another lot the churn and pails were not scalded. The results were compared and it was decided that water and temperature had more to do with the butter being bad than anything else.

At the Kansas State Agricultural College the butter was still further investigated, the results are given in full in Bulletin No. 138. This is an interesting bulletin and will repay careful study for creamery managers. I will try to tell you about the part of interest to us. The water used in the College Creamery is from the regular supply and is pumped from a well sixty feet deep and flows into a reservoir. The water used was all from this well and tank excepting that which came from the melting of ice. The ice used was manufactured and sold in the town by a regular ice company.

Testing the Water.

The samples were numbered from one to six and tested as follows:

1. Pasteurized, filtered, cooled. Tem 35. Bacterial count 10.
2. Pasteurized, unfiltered, cooled. Tem. 40. Bacterial count 40.
3. Pasteurized, unfiltered, cooled. Tem. 60. Bacterial count 1050.
4. Pasteurized, hot, unfiltered. Tem. 188. Bacterial count 50.
5. Pasteurized, hydrant. Tem. 60. Bacterial count 120.
6. Melted ice water from refrigator. Tem. 49. Bacterial count 800.000.

These tests were carried on from month to month, they vary according to the weather, while it was shown that the bacteria multiplied most rapidly in hot weather. The filtered water when the filterer was new was at its best, at first it removed from a quarter to a half of all the bacterial contents. Later the filterer failed to remove them all, and still later it became a source of contamination.

Temperature.

The raising of the temperature of the water also increased rapidly the number of bacteria present. When the butter was washed with sterilized water it was found to sell better, from one cent to three cents per pound than the butter from the same churning when washed with unsterilized water. It was concluded that temperature of forty or fifty degrees retards the development of bacteria and reduces those in the water from one-half to a quarter. The water used for washing butter should be sterilized, cooled and used at once and not allowed to stand around to collect a lot more bacteria.

Thoroughbred Berkshire Boars and Sows

A filter that has not the sand and charcoal renewed at frequent intervals is a source of contamination. Wooden tanks are often alive with bacterial growths. The drippings of ice water are saved in many places to wash the butter. They are unfit for the purpose.

Lactic Acid.

The lactic acid bacteria, or as it is scientifically called B. acidi lacterci, Nos. 1 and 2 and B, lactic aeroenes.

These common lactic forms are not numerous in fresh milk but at 70 degrees develop with great rapidity. The commoner classification of milk bacteria is made by the way they act on the gelatines. These are called the rapid and the slow liquifiers. Every cook has had the gelatine she made for her dessert fail to be firm, and has had it turn to liquid after half stiffening—this is bacterial, often caused by placing the gelatine at an open window where the dust laden with bacteria has struck it.

The so-called rapid liquifiers are relatively few and the active lactic acid bacteria soon destroys them. If they were left alone they act on the protein of the milk and produce putrefaction. This is the reason why milk may be kept at a low enough temperature to keep the lactic acid bacteria from acting, or as we may say keep from souring and yet be unwholesome, yes, even poisonous from the ptomaines that the bacteria have produced as the results of their life processes.

The Other Kinds.

The bacteria that are slow to dissolve gelatine are the producers of enzymes. When these are in any quantity the milk is not fit to use as the cause is filthy, dirty cows and stables and milk vessels that are not scalded.

The worst of those that trouble the farm butter maker is the slimy ones that grow in stagnant water. These are often brought into the milk pail from the dried dust clinging to the cow's udder. The cow's delight is to stand in water. This bacteria has also been found in the wooden tanks used on many farms to hold the water pumped up by the windmill.

I have known farmers' wives whose butter had commanded a high price that suddenly met a Waterloo in a dose of this bacteria. The containers of the milk were all kept in the best manner possible as well as the cows and stables, yet the butter was not to be eaten. One case I told you of last week where the stone jar used to hold cream was at fault.

The Farmer's Wife.

When a woman has always made good butter I know of no greater humiliation than to have every churning go bad and from no apparent cause. If it does happen the first thing I should do would be to have the meadows looked over and if there were any pools have them fenced up so that the cows could not wade in them.

Then examine the watering troughs at the barns, and as a precaution have them whitewashed inside. At the house have the water tank cleaned out and whitewashed inside. There is something else that perhaps you have never thought about. That is the amount of dust that blows into the uncovered tank. Make a cover out of cheese cloth, sew it together and if the tank is a wooden one it can be tacked to place.

If the tank is metal then sew a lot of burrs to it; these iron burrs are cheap and useful for weights. The dust and dirt that falls into a water tank as well as the moths, sometimes a bat or an owl is found drowned; the death may be as tragic for the household as it was for the owl; these the cloth will keep out and yet the air will be allowed to penetrate, for unaired water soon becomes foul.

Clean the cows and whitewash the stables, then give the milk vessels an extra scalding for luck. Then go to your neighbor and beg a little good buttermilk or good cream, and add it to your cream twelve hours before churning time. If this last seems to you unnecessary—DO NOT FAIL TO DO IT. I had for some years to help the other creamery out here with the skimmed milk and buttermilk, for they were making their butter from all kinds of milk while I had just my own two hundred and fifty cows' milk to handle. It will do it every time by starting a good bacteria from a clean source to take the place of the bitter, rancid producing one from an impure source.

MULE BEATS HORSE.

While the horse goes on kicking holes in the sky with prices that make one's head swim, his modest half-brother is breaking a few records himself.

An increase of 5 to 10 per cent. in the volume of trade in mules is shown for the year 1906. As in horses there was a record-breaking demand, and more mules were shipped South than ever before so far as there has been any record kept on the business.

The Kansas City, Mo., market reports showed a very substantial gain over 1905, and values held wonderfully steady throughout the year. The receipts were not only increased, but the outlets of the Kansas City market were enlarged.

A very significant feature was the enormous demand for mules for railroad work. This fact has been forcing itself upon the attention of dealers for several years. It was thought that this demand had touched the highest point in 1905, but the demand was even stronger last year and the 1905 record was smashed. The construction of railroads last year was heavier than the year previous, to which fact may be due the increased mule demand. The shipment of mine mules also surprised the natives.

Just at present hands are reaching out from all quarters for the coveted mule. It looks as if they will go on reaching out. There seems not a single indication that does not point to the fact that the record of the present year will even surpass the remarkable demand of 1906.—D. R., in Farm Progress.

SCRUB FEEDING.

You may have the best cows in the world, but if you do not feed and manage them properly they can never be made to pay. One advantage of having pure-bred cows is that it leads one to practice pure-bred feeding. There is such a thing as scrub feeding as well as scrub stock. When a person gets a good cow he is much more likely to take good care of it than he is of a scrub.

Cream Separators, all sizes, all prices. See O. J. Weber Co., 555-557 So. Los Angeles St., Los Angeles.

Help the Horse

No article is more useful about the stable than Mica Axle Grease. Put a little on the spindles before you "hook up"—it will help the horse, and bring the load home quicker.

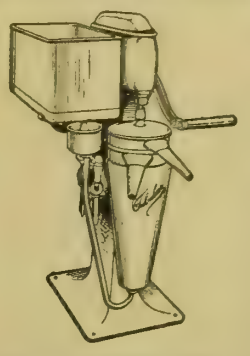
MICA AXLE GREASE

wears well—better than any other grease. Coats the axle with a hard, smooth surface of powdered mica which reduces friction. Ask the dealer for Mica Axle Grease.

STANDARD OIL COMPANY Incorporated

Because You Need The Money

It's your business and if you don't attend to it, who will? You cannot afford to keep cows for fun. That isn't business, and, furthermore, it isn't necessary. There is money in cow keeping if you go at it right, and besides there is more fun in going at it right than there is in staying wrong.



You need a Tubular Cream Separator because it will make money for you; because it saves labor; because it saves time; because it means all the difference between cow profits and cow losses.

Look into this matter; see what a Tubular will do for you and buy one because you need it.

How would you like our book "Business Dairying" and our catalog B. 260 both free. Write for them.

The Ornamental Garden

By ERNEST BRAUNTON

GARDEN OF GETHSEMANE.

THIS is the scene of so many events forever memorable in the history of our race, the battle ground and point of attack alike of the Assyrians, Romans, Saracens, Crusaders and Turks.

The walls of Jerusalem with the dome of the Mosque of Omar upon what is believed to have been the site of the Temple, form a pleasing background to the picture, while under the walls is the Mohammendan burying ground, whose turban surmounted tombstones mark the last resting place of the male of this turbulent race, while that of the poor female is simply capped with an insignificant ornament, the whole place bearing a look of neglect and totally devoid of trees.

The time of day usually selected to visit this spot is toward evening, when the red light of the setting sun glances over the city, touching its domes and minarets with a last dying gleam and the dreary hills are broken into grand masses of purple and vermillion, while the glen below the valley of Jehosaphat, where is the dry bed of the brook Kidron; here sleep millions of the sons of Isreal almost side by side with their enemies, the Moslems, for both believe that the last judgment is to take place here, and in places it is fairly paved with the sepulchers of the Moslem or the simpler slab of the Jewish tombs. And the place of the sad groves which shrouded the agony of Christ are sinking into the shades of night. If we climb to the top of the hill and look eastward we see over the far horizon the mountains of Moab and the valley of the Jordan with the Dead Sea and the desert glowing in the sun's last rays; this completes the indelible impression a scene that for its association is unequaled in the world.

And the picture is remarkable chiefly for these suggestions of the past, for horticulture is not encouraged in the dominion of the Sultan, and only a small fraction of the arable land is under cultivation, owing to the absence of roads and the pernicious practice of farming out the taxes, which, in its practical workings, is a most ingenious and pitiless system of robbery.

The Garden of Gethsemane has but few trees; we recognize the cypress and the olive, two or three of which are very old but as we read that Titus cut down all trees about Jerusalem and that a legion encamped at the foot of the Mount of Olives, it would suggest that they were planted by Christian hands to mark the spot, unless, like the sacred olive of the Grecian Acropolis, they may have reproduced themselves; this in spite of the old tree in the picture, the so-called "Tree of the Agony."

The trees themselves remind one of the celebrated cedars of Solomon on Mount Lebanon in the disproportioned hugeness of their venerable trunks and to their foliage above. For ages the pilgrim has knelt and kissed them with tears, carrying thence a few of the scattered fruit or a portion of the bark to remind him of the spot.

The garden is surrounded by a high stone wall, a broad path leading around its entire area, while the portion containing the trees and flowers is protected by an iron railing with sharp pickets. The interior is subdivided by numerous wooden fences with no apparent reason.

Many plants in pots are employed to set off these spaces with the purpose of frequently changing and ensuring a constant bloom. The flowers are chiefly annuals. Daisies and hollyhock are prominent. The whole is extremely formal and devoid of beauty, but presents an abundance of color, which pleases the throngs of pilgrims who cheerfully pay the entrance fee to worship at the various shrines and who frequently form a continuous procession through its walks during the daylight hours.

The olive is still scattered about the Mount of Olives and a few half cultivated figs and pomegranates assist in recalling the past, It is through the branches of these trees that the more picturesque views are seen and we think of the time when these terraced hillsides were once clothed with verdure, but now denuded even of their soil; thus has the oppression of the unspeakable Turk peeled the land that once "flowed with milk and honey."

FLORICULTURE.

What are flowers good for? What could they have been created for, is a question that we hear repeated from youth to hoary age.

To the great mass of people who propound such an interrogation, the flowers may be spoken as noxious weeds; as plants good for nothing. Then as we begin to rise in the scale of manhood, we can begin to think of framing an intelligent answer—that flowers are good for pestiferous goats to eat.

We, who attempt to cultivate flowers in the city, where we are sure manhood is developed as far as the goat element, can postively affirm that we know flowers are good for something for goats to eat. We have frequently such positive and ocular proof that flowers were not formed in vain, that we can say positively that we do know that flowers are good for something.

Advancing a step beyond this position, where sight is lost in faith, we tremblingly suggest that flowers were not formed in vain, because they are beautiful. There is power in beauty. Therefore the tiniest flower that blossoms in the noonday sun is a thing of power.

The Creator has numerous forms of power, and the beauty that responds to an educated eye from the petal of many lines is a power that can move the world. There is beauty in a crystal teardrop; and it is balanced only by a mighty "power behind the throne." There is beauty in the glowing sunbeams, and who can compute the power thereof? "A thing of beauty" has not improperly been called "a joy forever."

IT'S PENNY WISE.

Policy to set out a good tree, costing good money and then let the sun burn the bark or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Manufacturing Company, 2124 Willow St., Los Angeles.

The Vegetable Garden

By ERNEST BRAUNTON

VEGETABLE GARDEN POINTERS.

NO weeds should at any time be allowed to mature seed. If this is carefully attended to, there will be in one or two years quite a decrease in the number of these pests.

Rotation should be practiced with system in every garden; not alone for the soil's recuperation, but also to lessen the attacks of insects and fungous diseases.

The various vegetables, whether grown for market or home use, occupy the soil different lengths of time, making it possible to produce half a dozen different crops each year, for in California, by proper fertilizing, we may keep the garden filled.

ROTATION OF CROPS.

Dr. Oemler, in "Truck Farming in the South," in discussing rotation of crops, says:

"Neither the areas nor the varieties of crops of the truck farmer are sufficient to enable him always to practice regular courses of rotation; nor should a lack of manure ever compel their strict observance, but he should aim:

"First—To have a crop which succeeds another as dissimilar in composition and the demand it makes upon the soil as possible.

"Second—Never to have plants of the same family succeed each other. For instance, melons should not follow cucumbers, tomatoes should not follow eggplants or Irish potatoes; beans should not succeed peas, or vice versa.

"Third—Tuberous plants should not be allowed to follow plants of the same character.

"Fourth—Roots should not succeed root crops, as turnips, beets, etc.

"Fifth—Deep or tap-rooted plants should succeed others of dissimilar growth.

"Sixth—To make the heaviest application of manure to such crops as require most, as cabbage, onions, etc., and have other crops succeed these requiring less, as tomatoes, eggplants, etc., so that the whole farm may be gradually brought to the same degree of fertility."

Other benefits of rotation are the destruction of noxious weeds and paracite fungi and insects.

TOMATO CULTIVATION.

Cultivation should begin soon after the plants are transferred to the field. If both the rows and checks are straight, plow cultivation will be facilitated, leaving but little for the hoe. A 24-inch heel sweep will do the work admirably, as such an implement can be run nearer the plants than any other without bruising.

The wings of the heel sweep extend over the vines and after they have spread over a portion of the row, stir the soil and destroy the weeds where no other plow can reach without injury to the vines. It leaves less work for the hoe, and at the same time gives level and shallow cultivation. The roots of the vines should not be broken, particularly after the first blossoms appear, but shallow cultivation should be continued until the first fruit ripens, and after, if the soil threatens to become dry or weeds appear.

CABBAGE SOIL.

The cabbage is a gross feeding plant and requires a rich, deep and mellow soil heavily manured to produce the best crops. A mellow loam with clay sub-soil is preferable, but sandy loam will give a good crop. Good drainage is essential, and particularly to the early spring crop. Heavy lowlands, no matter how fertile, rarely produce a good early crop, nor is new ground good.

The average garden soil that has for some years been in a high state of cultivation will produce a good crop. A slight northern exposure will frequently give better results for the extra early crop than a southern, as the former is not subject to such marked changes of temperature. Deep and thorough preparation is as essential as an abundance of plant food and good cultivation. Rotation is necessary, and cabbage should not occupy the same soil twice in succession, nor should any plant of close botanical relation be grown on the soil in the meanwhile, such as cauliflower, mustard, kale, etc.

ONION SOIL AND ITS PREPARATION.

The best soil for onions is well drained, sandy loam with clay subsoil, and containing an abundance of humus. The field should be nearly or quite level, and freed from all roots and trash. Soil that has been under high cultivation for a number of years is preferable.

No matter how fertile the field may be in its owner's estimation, he cannot expect the best results until it has grown onions for several years, and in the meantime kept free from all weeds and heavily manured for each crop. As onions may be grown on the same soil for any number of years, and under equal conditions, will each year give a better yield, it follows that this crop should be an exception as regards rotation of soil.

A rotation of manures will be needed, however, and particularly so if commercial fertilizers are used to any considerable extent. This rotation is secured by either stable manure or green manuring, or both, when commercial fertilizers have been extensively used and vice versa. As the onious are harvested in June or early in July, ample time remains for a crop of cowpeas to be grown and plowed in, and the soil prepared for the fall sowing of seed.

It is of the utmost importance that the land be plowed, harrowed and rolled (and raked if necessary) until it is brought to the best possible condition. The manure which has been so manipulated to free it from all lumps and litter is evenly distributed broadcast and worked into the soil. The preparation should begin some weeks before planting time, that there be no mistake as to its being properly done. Clean culture the previous year will be a great saving in the preparation and cultivation of the next crop.

The peach crop about Salinas is very spotted; good yield reported in some orchards, while in others the outlook is very poor. Taken altogether, estimates run all the way from 25 to 40 per cent. of a crop. Hill orchards are showing up far the best

TOMATO TROUBLES.

The use of the Bordeaux solution proves an effectual means of holding the tomato leaf blight in check.

In 1896 spraying with Bordeaux solution four times produced, with 35 varieties, an average increase in yield of 2.5 tons per acre of marketable fruit.

In 1897 spraying with Bordeaux solution three times produced, with 19 verieties, an average increase in yield of 2.2 tons per acre of marketable fruit.

Some varieties are more susceptible to the blight than others. In 1896 all but one variety, and in 1897 all but three varieties gave an increased crop of ripe fruit as a result of spraying with Bordeaux solution, and all of the varieties showed an increase when the amount of green tomatoes at the end of the season was added.

The increase in crop as a result of spraying, ranged from 1-4 of a ton to 6 tons in 1896, and from 1-4 to 4-1-4 tons in 1897.

THE RIDDLE.

Life may be a riddle—
Half a dream and doubt.
But the music's in the fiddle
If you just can get it out!

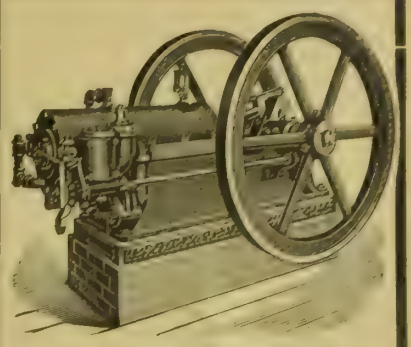
Anyway you take it,
Life's in your control;
World's just what you make it,
So—let the music roll!

Hear those bells a-ringin'
Best that they can ring?
Hear the sweet birds singin'?—
Follow suit, and sing!

Out of fifty-three samples of milk seized in a recent raid, thirteen were reported on unfavorbaly at Thursday's meeting of the Board of Health of San Francisco.

A husband may forget the bird
When wifey leaves the city;
But seldom does the lonely man
Forget to feed the kitty.

'Twas overstudy ailed the star,
The paper said, but when
Her understudy made a hit
She got right well again.



LAMBERT ENGINES

Are Superior to All Others

No Leak Cylinders
Cast in one piece with water jacket—no joint to leak—no gasket to blow out

Double Water Circulation
Prevents unequal expansion and contraction

No Gaskets to Blow Out
Ground joints only used

Insulation
Cannot wear, burn or blow out; it is permanent and indestructible

Economy of Fuel
We cannot claim that the "Lambert" will use 50 per cent. less fuel than some other engines, but we do guarantee that it will produce as much power for each gallon of distillate used for one year, or five years, as any engine on the market. This does not sound so big but means more

No Unreasonable Claims
The Lambert is not a "has been" or a "ging to be"; its record, past and present, speaks for itself.

Does this stream of water look good to you?
It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.
It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.
How many pump users can say this?
It shows conclusively that it pays to install good machinery.
We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it.
Mail us a card asking for it today.

California Horticulturally

By JOHN ISAAC, Sacramento, California

GOOD FRUIT TREES.

WHILE, at the present time, there is every reason to look for a fair to good crop of deciduous fruits, information from Eastern fruit-growing sections rather indicate that there will be a good d mand and good prices for all that California may have to sell. There have been very heavy frosts over a great part of the East at the time when the blossom buds were swelling, and it is reported that the losses will be heavy in consequence, and that little fruit will be produced this season. This means that California will be called upon to supply the shortage, and that our fruit growers may look for a prosperous season. Of course, we sympathize with our Eastern orchardists, but at the same time we are glad that we are all right and will have fruit to sell.

NO CHANGE IN HORTICULTURAL LAWS.

Of numerous horticultural bills introduced in the last Legislature, but one, that defining the length of the official life of the county horticultural commissioners as two years, received the Governor's signature. The one raising the compensation of the local inspectors from $2.50 to $3 per diem passed both houses, and, it was thought, would become a law; but it failed to receive the Governor's signature within the alloted time and so perished. All the horticultural laws remain as heretofore, therefore, with the exception that the county commissioners have a tenure of office for two years instead of for an indefinite term, as heretofore.

DESTRUCTION BY DREDGER MINING.

There is a growing distrust of the dredger miner in the upper country, and an inevitable conflict between him and the agriculturist looms up in the future. It is a sickening sight to the man who is not profiting thereby, to see beautiful and productive farming land destroyed for all time, and piles of unsightly cobbles left where orchards and vineyards throve. The gold that is removed from the soil leaves the State, but the rock piles will remain forever, and farming land which might be profitable to future generations for untold time is left a barren waste. For the immediate gain of a few moneyed men, future generations are being despoiled of their rights, the State is being deprived of taxable property and the State is loser in every respect. Dredger mining is more desructive than hydraulic mining, and that has been stopped.

THE FIRST CHERRY SHIPMENT.

The fresh-fruit shipping season has opened and, as usual, Vacaville is in the fore with the first shipment. This consisted of a box of cherries grown by T. Lee Gates, and it was forwarded through the Fruit Distributors on the 23d inst., about two weeks later than the first box shipped last year. The first carload of cherries will go forward in ten days or two weeks.

LOWER FREIGHT RATES.

Deciduous fruit shippers have been favored by the railroads this season by a reduction in freight rates on fruit of ten cents on each hundred pounds. The probable shipments of fruit from Northern California during the present season will, it is estimated, amount to about 7000 carloads, and this reduction will average $25 for each car, or a total of $175,000 for the season. This is an important item saved to the fruit shippers of the State.

PLANT BREEDING.

A correspondent of the Southern Agriculturist says:

"No single line of investigation is receiving more attention at present than plant breeding—the improvement of domestic races of plants by crossing and selection. The general public had failed to recognize that, making allowance for certain well defined differences in structure and manner of life, plants respond to the same basic laws of reproduction that apply in animal breeding. We had regarded the occasional appearance of a new plant as something fortuitous — beyond control. Then came Burbank. And the magazines told such marvelous stories of his methods and results that we were in a fair way to imagine that the result of every cross, accidental or studied, would give to the world a new horticultural wonder.

Very few men become famous either as plant or animal breeders. The Durham cattle long have been a popular beef brand, and doubtless thousands of men have studied the type and worked carefully with it; but Bates, Booth and Cruickshanks are the names suggested when the Shorthorn is mentioned. Plant improvement is in a way more recent, and the men who have succeeded in it are so few that a great leader will be regarded as a wizard. The world has only known one Burbank, but there are in America today a number of careful plant breeders, and the sum total of their work means far more to the agriculture of the country than the productions of the great Californian. For they are not only endeavoring to produce valuable new plants, but they are patiently studying the laws on which all plant improvement rests, and they are giving widespread publicity to this fundamental knowledge. Haves and Hopkins and Hansen, Webber and Lyon and Emerson—to mention only a few of the experimenters whose work has attracted wide attention, each engaged in a special line of plant breeding, all are working in harmony. Already far-sighted business men are following in the lead of these practical students, and we have in corn breeding a well established business. The corn plant is being subjected to much the same treatment as has resulted in the establishment of well recognized families of Shorthorn cattle. It will not be long before the catalogues will list as many strains of dent corn—rather let us say of Leaming or Hickory King or other variety of dent corn—as they now contain of varieties of that plant. In the past the Experiment stations have been the butt of more or less good-natured ridicule on the part of the farmers, but had they accomplished nothing more than the work already done in plant improvement, they would have abundantly justified their existence."

Never expect the foal to eat with the mare, but always provide a small box in the opposite corner to feed the foal in.

With the Citrus Growers

By J. W. MILLS

WATER SUPPLY.

It was only a few years ago that the question of the water supply in some of the orange growing districts of Southern California was a very serious consideration. It got to a point where money lenders were calling in their loans and readjusting them on a lower valuation. The action of these men was a good indication of the real condition of the industry. The foundation of the industry is water. This was dropping rapidly in the wells in the majority of the choicest orange growing sections, and in some places it was getting to a point where the expense of pumping was about equal to the net profits. Every year saw the water receding in the wells and no one knew just where the end was to be. There was doubt in the minds of some if the subterranean reservoirs from which this pumping was done, would ever fill up again. No one knew how long it would take to fill these underground gravel beds which supply the various wells in certain sections. It might have taken one or two years and it might have taken one hundred years. In the first case, a few wet seasons would replenish the wells. In the latter it would have been a losing proposition to lay plans for future development or a continuation of operations. The last few seasons of bountiful rains have forever set at rest the uncertainty of the question. It is known all along the line that the water has risen more or less in all the wells where there was a continual lowering of the water level. What is still more gratifying is the knowledge that the waste water that runs off into the sea every winter, even during the driest winters, may be so distributed over some of the gravel deposits near the openings of the canyons that a large part of it at least may be directed into these subterranean gravel beds, thereby keeping up the supply for the wells. It is thus seen that the recent seasons of abundant rainfall have not only been of immense immediate value to the southern part of the state, but they have demonstrated that the future is safe even with a longer series of dry years than we have known.

KILL THE WEEDS.

It is not fully realized by most farmers that the weeds and grass that are often allowed to grow and go to seed in the orchards during the spring and summer take gallons of water from the soil every day. The only way to realize it is to sit down and figure it out. It will be observed if a "tumble weed," for instance, is cut off at the surface on a warm sunshiny day, that though it is quite heavy at the time, the next day it will be so light that its weight can scarcely be felt. It will not take a very great stretch of the imagination to realize that if it were possible to put it back onto the root and allow it to fill up with sap again, then cut it off again, repeating the operation every day, that many gallons of water would be extracted from that particular spot every day. Now if the weed were not cut off at all, but allowed to grow and exhale the moisture continually, much more water would be sent off, for no time would be lost in evaporation. Another significant thing is observable. When this and some other kinds of plants are cut off at the surface, the sap will continue to run out and wet the soil for several days, showing the extreme activity of the roots in taking in the moisture from the soil.

Grass, when first cut, contains about 75 per cent. of water. A light crop of grass will weigh about 1000 pounds per acre. That means 750 pounds of water, or nearly 100 gallons. At a low estimate it would be about 3000 gallons per month. Succulent weeds would use up a much greater amount of moisture. These facts show that it is very necessary to keep the summer weeds from growing. While there never is a very great amount in orchards that are regularly irrigated and cultivated, that have weeds growing in the spaces, but it is quite common to see trees with a heavy growth of weeds around the body of the tree all summer. Otherwise well-kept orchards often have weeds growing up through the branches year after year. It is no doubt a good plan to allow them to grow there during the wet season as the roots loosen the surface soil. It is quite an expensive job to clean these weeds out with a hoe. Any low built cultivator that does good work there.

THE KUMQUAT.

This is the smallest of the citrus fruits and has not heretofore been planted very extensively for commercial purposes in this country. It is supposed to have originated in Cochin, China, and is quite extensively grown at the present time in Japan, also in the districts of Fu-chau, Chusan and Ningpo, China. In Japan it is called Kin-kan, which means Gold Orange; Kumquat is Chinese for the same meaning. Botanists now know it as Citrus Japonica, although it has in the past been listed under various names by horticultural historians.

The tree attains a height of 10 to 12 feet, with a spread of top nearly equal to the height. It is very symmetrical in growth and produces an abundance of handsome fruits annually. The blossoms come during the summer and the fruit ripens during the late fall and winter.

This fruit has been introduced, in a limited way, in the markets of this country and, where properly handled, has brought very fancy prices. In packing the fruit, always clip little bunches of fruit with foliage attached and pack it in strawberry baskets. In northern markets it seems to sell better where the foliage is mixed in with the fruit, as Kumquats are often used for table decoration, and the leaves add greatly to their beauty. This is an advantage from the shipper's standpoint, as the leaves help fill up the baskets and make a larger volume than if the fruit is clipped off and packed by itself.

In China and Japan, Kumquats have been grown almost exclusively on Citrus trifoliata stock, to which they seem admirably adapted. We have propagated them in a limited way on sour orange and sweet orange roots, but they do not seem to prove very successful on these stocks. At the present time we are propagating them on both Citrus trifoliata and rough lemon stocks, and while they do better on the Trifoliata with us, there are some sections in which the Trifoliata is not desired and to which lemon stock seems to be admirably adapted. The Kumquat grows well on both stocks.—G. A. Taber, Florida.

ORANGE HISTORY.

"Tales of an Old Timer," in Los Angeles Express: I have been asked something about when oranges first made their appearance in Los Angeles, and from some data which I happen to have on hand am enabled to give the following: There were no oranges in the town of Los Angeles in 1837. About the year 1835, Don Luis Vignes, better known as Don Luis del Aliso, he of who I told you in a previous article, procured from the San Gabriel Mision two or three bearing orange trees and planted them near his house down on Aliso street, on or near the present site of the Maier & Zobelein brewery.

Don Luis had previously planted some orange seeds, which he may have brought from the Sandwich islands in 1831, when he arived in Los Angeles, or it is possible he might have got them at San Gabriel.

About the year 1835, William Wolfskill planted some orange seeds and raised a little bed of orange trees at his old vineyard on San Pedro street.

From this bed, or miniature nursery, came the trees which he first planted about the year 1838 in orchard form near his house.

About this time he also planted a nursery of oranges and some limes to the northward of his house. This piece of nursery ground was about 50x150.

About 1853, a Dr. Halsey planted a large nursery of oranges and limes on what was known as the Carpenter property on Alameda street. These he sold out to Wolfskill in 1857. The seed which Halsey planted, was, I believe, from Tahiti.

In 1859, Halsey planted another similar nursery, with the addition, I believe, of some flowers and, perhaps ornamental shrubs, on the Laughlin property opposite Wolfskill's. This nursery he finally disposed of to Mrs. Ogler.

VALENCIA ORANGE TREES

We have a quantity of first-class trees which have not been culled over, at reasonable prices. Also Washington Navel, Loquat Trees, Arbor Vitaes, Spruce, Cypress, Eucalyptus, Acacia, Pepper, Pine, Umbrella Trees, Roses, Palms, Etc.
Write for prices. Address
The Covina Nurseries, 1047 E. 46th St., Los Angeles, Cal.

Citrus Trees
TRUE TO NAME
And embracing all the standard sorts, are to be had of our establishment. Bear in mind that we are the largest growers of Citrus Trees in the world, and that our stock has been awarded the gold medal at every world's fair in the world where we have shown. Our fine booklet, containing 50,000 words and over 100 illustrations, gives you all the points on Citrus Culture. Price 25 cents. Can we send you a copy?
San Dimas Citrus Nurseries
San Dimas, Cal.

FRUIT TREES FOR THE ROADSIDE.

We have often been impressed in riding through California, by rail and otherwise, with the mistake that has been made by our people in not planting fruit trees along the roadway. Especially so in the northern and central portions of the state where irrigation is not so essential to the existence of trees. The sense of wasted opportunity is apparent and one cannot but regret that our people have not seen this mistake earlier. Just think what a variety and abundance there would be of fruit of the hardier varieties, had our early settlers improved their opportunity to line the miles of dull, shadeless roads with apple, plum and cherry trees, which not only would furnish beauty, but fruit as well. The cost would have been slight, the amount of care required small, the returns how large! In the neighborhood of towns and cities, also, the abundance of roadside fruit which the boys might be permitted, under slight restrictions, to pick up and eat at will, would have been a protection to private trees, which few persons now attempt to grow on account of the general apprehension that the boys, not the cultivator, would get the fruit. Riding along a road in Santa Barbara county recently, we noticed a strip of fruit trees on either side of the highway. We were told that these trees furnished a good deal of fruit, one year with another, and they certainly looked beautiful, covered with blossoms which fill the air for blocks around with an aroma fit for the gods to breath.

ENFORCE THE FOOD LAW.

Secretary Wilson has already taken steps to enforce the new food and drug law by appointing a commission of experts to look after it especially. The chairman of this commission will be Dr. H. W. Wiley, chief of the Bureau of Chemistry, and one of the most practical and capable men in the government service. The legal phases of the enforcement of the law will be looked after by the department's solicitor, George P. McCabe, and Dr. Frederick L. Dunlap of the University of Michigan will devote his time to the scientific phases of investigations into violations of the law.

As was to have been expected of so conservative and just a man as Secretary Wilson, there will be no unnecessary noise with respect to making effective the provisions of the new enactment. It has been freely charged that the manufacturers of whiskies have banded together for the purpose of fighting the provision which requires labeling of "blended" whiskies. Secretary Wilson claims to have no knowledge of such action, but is prepared for any opposition that may arise. "We will make no haste in the enacment of the law," said he, "and everybody will be given ample time to comply before any action is taken. The Civil Service Commission has not yet given us our inspectors, but we hope to get them soon. When they are in the field they will report on any case where the law is not being obeyed. The party violating it will be communicated with and asked if he intends to comply or if he wants a hearing. If he asks for a hearing he will appear before the board and state his case. If he ignores the warning or openly refuses to comply with the law, the matter will immediately be thrust into the courts for their decision. There will be no haste and no persecution, but a gradual tightening of the lines."

The new law has already been productive of benefit in restraining adulteration of food products and manufacture of unwholesome and dangerous drugs circulated as cure-alls; it is not too much to expect that a great deal more will be accomplished on behalf of the innocent consumer.

CULTURE OF THE OLIVE.

Closely associated with the culture of the olive is much ancient history as far back as the time of Greece and Rome. History records that the great olive trees yet to be seen around Tivoli, in Italy, were already old when Romulus traced with his plow the walls of Rome. Nearly three thousand years have passed since then, and yet the trees stand vigorous and productive. The same can be said of the magnificent olive grove that lies on the east side of Jerusalem, which gave to the "Mount of Olives" its name.

Among the Greek the olive was sacred to Pallas Athens (Minerva) who was honored as its bestower. It was also the emblem of chastity and the symbol of peace. Poets have sung its praises and historians have vied with each other in recounting its beauty and utility.

Historical records tell us that this precious tree was introduced into California in 1769, from San Blas, Mexico, during an expedition of Franciscans, sent to take charge of the Jesuit missions in California. It appears from the ship's manifest that one Jose de Galvez, who was Visitor-General, and secular head, representing the king of Spain, and Father Serra, proceeded to make arrangements for the establishment of new settlements and seemed to be far-seeing, for it was found that he had caused to be shipped to "Alta," California, flower, vegetables and fruit seeds for garden and orchard and grain for the field.

All the Mission orchards were very small and some had but few trees, but those trees play an important part in the horticultural history of our state, for they laid the foundation of a gigantic industry, and furnished stocks for many groves, which today may be styled the "prehistoric" orchards of the state. Thus the Mission Fathers builded wiser than they knew.

The culture of the olive for commercial purposes forms an industry that with proper protection, should be regarded as one of the safest in California, and under favorable conditions the most profitable of all branches of horticulture.

NO MORE DESECRATION OF THE FLAG.

The supreme court of the United States recently delivered an opinion sustaining the constitutionality of a Nebraska law to prevent desecration of the national flag. The decision is looked upon as settling definitely whether the states can constitutionally prohibit the use of the flag for commercial purposes.

The case was that of a firm of liquor dealers at Omaha who had decorated beer bottles with a representation of the Stars and Stripes. Under the state law they were fined, and took the case to the United States Supreme Court. That court, with one dissenting opinion, has declared that states may pass laws prohibiting the use of the flag for advertising purposes. Justice Harlan, who delivered the majority opinion, said that the use of the flag on beer bottles cheapens and degrades it, and that prohibitory legislation could not be considered an abridgement of personal rights.

"This decision," says the Spokesman-Review "will be welcomed by many people all over the country, and by none more than by officers of the army and navy who have long been advocating for the entire nation a law such as Nebraska has. Objection has often been taken to various uses to which the flag has been put, but on the other hand it has been and still is argued by some that the flag, being the common property of the people, can not be used by some and denied to others. It is contended that if an inscription of a patriotic organization can be placed upon it any other private use can be made of it. The supreme court holds, however, that where such use is degrading it can be prohibited. The decision will appeal to the patriotic sentiments of all loyal citizens."

The decision of the supreme court will curtail the use of the flag on many advertising propositions, the only virtue of which was the stars and stripes which incircled them.

AMENDED CHILD LABOR LAW.

The Cultivator has been requested to state what the present form of the child labor law as amended by the legislature is.

Section 5, as amended reads: "Nothing in this act shall be construed to prohibit the employment of minors at agricultural, horticultural, viticultural, or domestic labor, during the time the public schools are not in session, or during other than school hours. For the purpose of this act, horticulture shall be understood to include the curing and drying, but not the canning, of all varieties of fruit."

It will thus be noticed that minors may be employed in curing and drying fruit, but not in canning the same.

USE THE CULTIVATOR.

About the time we think we have got rid of all the weeds from last winter, a new order will begin to show above ground from seeds left in the soil from last summer's crop. If the ground has been kept clean for several years and no weeds gone to seed, it will be comparatively easy keeping down the weeds for the summer season, but if any quantity have been left to seed warm weather will be sure to bring them up in all the irrigated districts. Elsewhere it will be a comparatively easy matter in view of the dry season. The cultivator must now be kept going at all seasonable times, both on dry and irrigated lands.

PLANNING A CROPPING SYSTEM.

Continued from First Page

Fortunately, the farm described in Farmers' Bulletin No. 272 has shown that soy beans are not only an excellent hay crop in that section, but that they may be planted as late as the last week in June. This fact suggests rye as a winter hay crop. Only 2 acres of this need be used for hay, since only 7 acres of hay are needed and the soy beans furnish 5 acres. The remaining 3 acres of rye will be convenient for bedding. Accordingly, the following two-year rotation was laid out for two 5-acre fields: First year, corn, followed by fall-sown rye; second year, rye, followed by soy beans.

It is hoped that ultimately it will be possible by the study of farm practice on the best farms to arrange rotations in all parts of the country based entirely on successful local practice.

While this office can not undertake to furnish detailed plans for an indefinite number of individual farms, at the same time we desire the opportunity to do a considerable amount of work, in order that we may test the possibilities of certain types of farming and enlarge the number of highly successful farms, so that we may have more material for the study of farm management. Ultimately it is hoped to formulate generalized plans for farms of various types in all sections of the country, and to make these plans available in our publications.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Army worms at Whittier are attacking both lemons and oranges.

Fullerton is at least 150 cars behind on her citrus shipments.

The walnut crop of Ventura county will be a big one this year, and prices will be high.

There has gone to date from Highland, West Highlands, Patton and East Highlands 1210 cars of oranges.

The Placentia association has shipped about 100 carloads of oranges and is twenty-five cars behind on account of car shortage.

The six or seven orange packing-houses at Fullerton are far behind in the season's output on account of the great car shortage.

The past week has been a banner one for orange shipments from Redlands, no less than 203 cars of 362 boxes each going forward.

Oranges brought to the Placentia association packing-house show that worms, a good deal like the army worm, are boring into the fruit.

The Wilson Fruit Company of Fullerton has shipped sixty cars of oranges this season, and is forty cars behind on account of the car shortage.

The Bureau of Animal Industry of the Department of Agriculture is entering upon a new war for the extermination of sheep scab in California.

Reports from various parts of the state are to the effect that the bees are making very little honey, and in some localities they have to be fed to keep them alive.

Reports from all over Southern California are that thus far, this season has been a record breaker in citrus fruits though it has not been as good as to deciduous fruits.

The Citrus Union at Fullerton has sent out 120 carloads, and is only about thirty cars short, having also hauled thirty carloads to Anaheim for shipment over the Southern Pacific.

Redlands rain is 23.32 inches, a total that has been exceeded only once since Redlands was founded, and has been exceeded but three times since 1870, since rain records began to be kept.

The Gregory Fruit Company of Colton has bought nearly the entire crop of apricots and peaches in the Hemet valley, paying $50 per ton for apricots and $50 per ton for peaches, taking the whole crop.

Every one is very busy at the Tustin packing-house this week. They have been working nights as well as days. Five cars of sweets and navel oranges and one of lemons have been shipped this week.

Taking the estimate that was made at the first of the year by a number of shippers, there are yet in the neighborhood of 210 cars of navels, and other varieties of oranges and lemons to ship yet in the Highland district.

While the heavy rainfall made the southern walnut yield an immense one, it also brought on the blight heavily, and it is considered that, on the whole, the returns to the grower will be no greater than in other recent years.

Fire destroyed the California Citrus Union and Rialto Orange company packing-houses at Rialto, causing a loss to the Citrus Union of $8,500 and to the Rialto Orange company of $13,500, and to Arthur Gregory of Redlands, $5000.

Information has been received from Horticultural Commissioner S. A. Pease that the worms have made their appearance at Highgrove between Colton and Riverside. In this section the worms killed 50,000 orange in one grove last year.

The new town of Wilmar near the San Gabriel Mission will have a denaturized alcohol factory, the erection of which will cost $160,000. The plant will occupy eight acres of ground and will utilize cull oranges, potatoes, sugar beets, etc.

HORTICULTURE.

Dan Myers has over a thousand young turkeys on his ranch west of Hemet.

The army worm pest is becoming more serious south of town and is appearing in some gardens in Pomona.

The prospects are that there will be a light hay crop in the San Dimas section, owing to the absence of late rains.

During last week shipments over the Southern Pacific amounted to forty-seven cars, mostly cabbages and oranges.

There is an abundance of dew feed and sunshine is all that is needed to give a record breaking crop in the south.

A car of oranges, the first iced with ice from Hemet's ice plant, was shipped from Hemet last week by Worthley & Strong.

The cabbage season is in full swing in the south now and for some time to come the vegetable will be shipped as fast as cars can be secured.

The Espee will not receive cabbages or oranges at Fullerton or Placentia, compelling growers to haul the product to Anaheim to be packed.

The first crop of alfalfa at Hemet has been cut and brought about $9 a ton. There is a good stand of the new alfalfa planted this season.

Although the bees in the interior are faring better than those nearer the coast, the present cloudy weather is very discouraging for bee men.

Redlands is again being visited by the army worm pest, the appearance of which at certain points in the valley was reported a few days ago.

Willow springs can boast of the first hay cutting of the season in Antelope valley. The first crop averaged a little over two tons to the acre.

G. M. Frazier is putting ten acres of peanuts and thirteen acres of sweet potatoes; John Miller is planting twenty acres of peanuts and twenty acres of sweet potatoes, east of Hemet.

Jacob Stoner has recently shipped from his ranch in Heber, in the Imperial country, to Los Angeles, ninety-one porkers for which the Maier Packing Company paid 8½ cents a pound, a total of $1,342.45.

One of the newest manufactories to be planned for Southern California is an egg factory, operated on an enormous scale. The machinery to be used will be 25,000 laying hens, and the product will consist of fine fresh hen fruit.

Twenty-one carloads of cabbage and sixteen carloads of oranges were shipped from Anaheim during the past week. Three carloads of cabbage will be shipped daily from here during the ensuing week, the price received being $17 a ton.

Day by day the grain harvest is getting into swing, says the Imperial Standard. The machines now under headway are mainly binders, but the headers are being set at work and the owners of the great combined harvesters are getting them into shape.

Eight cars of onions have been shipped to date, from Thermal, says the Submarine, and while only positive returns have been received on three, there is every indication that all will average three cents net to the growers, after paying for the crates.

Numerous fruit buyers are at Hemet for the purpose of buying the apricots. They are offering $30 a ton for green fruit. Orchardists are very fortunate in getting so high a price as there is an elegant crop of 'cots. Some of the groves are estimated to yield eight tons to the acre.

The orange crop of the Ojai Valley, Ventura county, has this year been a remarkably fine one, and the growers have obtained top-notch prices for the output. The Ojai oranges ripen about a month later than oranges in most sections of California, and this fact gives the fruit raised there an advantange. There has been no shortage of cars reported.

Northern California

AGRICULTURE.

Haying will commence early in Bennett valley and the crop will be a light one.

The farmers in the Alexander valley and Dry creek valley are fighting caterpillars at the present time.

In alfalfas, fifty-five varieties have been received, and are now under propagation at the Chico garden.

Sulla grass, from the European countries, and a rival of alfalfa, is also being experimented with in Butte county.

A Bennett valley correspondent writes that the good weather has had the effect of making crop conditions improve.

A number of the farmers of Meridian and District No. 70 have organized to build a new and modern creamery.

In parts of Central California, taking the country as a whole, no amount of rain will make the crops what they were last year.

A large amount of hay, principally alfalfa, is being shipped from Kerman to the splendid markets of Los Angeles and San Francisco.

The Libby, McNeil & Libby cannery, just below Isleton, is about completed. They are about ready to can asparagus, fruit and vegetables whenever these are ready.

The Monterey county grain crops on the south side of the river will be short. They are suffering greatly for rain. The later sown crops look better than the early sown.

Crops about Soledad will be short, the surface of the ground is so baked. Nearing Gonzales crops seemed much better and there are some really fine fields of grain, especially late sown grain.

In all cases, say the Sacramento hay balers, wood for cook house, feed for horses, water and air are to be furnished the baler. Many presses may not press on account of scarcity of men.

The weather has been so cool that the bees could not gather honey. They start out in the warm part of the day and the cool breeze coming up in the afternoon chills them and they are unable to reach their hives.

The ground in Monterey county is baked so hard it seems to pinch the grain off at the surface. It has a short growth and the heads are very short. The yield will not equal that of last year, even if we have rain immediately.

An important experiment is being carried on in the North with African para grass, and this may prove in time to be of the greatest benefit to certain sections of California. This grass is raised in some sections in preference to alfalfa.

The Japanese matting grass plants, the obtaining of which brought so much trouble to Special Agent Tull, have been planted in the open in Northern California and will be retained until next winter, when they will be transshipped to other parts of the United States.

A novel implement for use in beet sugar culture will be shipped from England in a few days to the Alta California Beet Sugar company. It is an immense plow with steam engines such as are used for plowing in beet fields of Europe. The entire outfit costs approximately $25,000.

Elwood Mead, of the Department of Agriculture, has been in Fresno conducting experiments in regard to alkali drainage. He believes that great things are to be done with lands which have long lain waste because of alkali when the system of alkali drainage comes into practice.

The hay-pressers of Yolo county held a meeting Sunday and entered into an agreement to maintain the following prices for the season of 1907: Pressing hay and bucking from shock to press, $2.50 per ton; pressing from stack, $2.15; pressing where wire is furnished, $1.80; pressing where board and wire is furnished, $1.50.

HORTICULTURE.

Estimates of the Vacaville prune crop range from a fifth to a third of a crop.

The Fresno Republican states that buyers are paying $40 a ton for apricots on the tree.

An organization of apple packers has formed under the name Watsonville Packers' Association.

The fruit crops in Placer and Siskiyou promise to be good owing to cold weather keeping the trees back.

The Southern Pacific Co., expects to put on a berry and fruit train from Watsonville to San Francisco in about a week.

Apricots about Vacaville will be very light; probably from 2 to 5 per cent. of a crop. This, however, is better than last year.

Tehama county has the promise of the banner fruit crop this season of all varieties, including the peach, prune and almonds.

All over the north grapes are doing well, and good results are looked for.

Lindsay has shipped over a hundred cars of oranges since Jan.

Cherries in the Vaca valley—Early varieties light; later varieties good. Tartarians, which follow the earliest varieties, will also be light.

The big cannery associations have had their representatives around Winters this week, and a few sales of apricots at $60 are reported.

The apricot crop in Fresno will be better in quality but about the same in quantity as last year. The canning season will open about June 1st.

The orchards on the Buena Vista all show strong evidence of too much rain; consequently mildew, curly-leaf and different fungoids are coming on.

In King, Tulare and Fresno the crops will be fair to good. That of apricots fair, peaches better than last year while there will be a good prune crop.

Generally speaking, the later varieties of plums have a fair crop in Monterey county while the early ones are short with the exception of Climax.

There are many thousands of caterpillars in the orchards of northern Sonoma, and if it were not for the activity of the farmers they would do untold damage.

The tragedy prune crop in Vaca valley is a failure. This is one of the best shipping plums and there is probably a larger acreage devoted to them than any other variety.

The peach crop throughout the San Joaquin valley is good and the price for the fruit will be strong. In fact, indications are that the prices for all kinds of fruit will be good this year.

Yolo county reports conditions not so bad as had been reported. The yield of almonds and apricots is spotted. The crop of early peaches will be light, but there will be big crops of the late varieties.

The California Fruit Canners Association is going to pay fifty dollars a ton for the blackberries which they have contracted in the Sebastopol section, although the contracts call for only $45 per ton.

In the Sonoma county hills, four miles north of Healdsburg, is a ranch of 630 acres belonging to the Salvation Army, and on which homeless boys and girls are reared into strong, honest men and good industrious women.

The heavy rains destroyed a great deal of the bloom of the early crop of northern fruits. The pear crop, from present indications, will be unusually large. The prospects are also good for an average crop of both prunes and plums.

Otto Michelson, superintendent of the Alexander valley winery, estimates that in the neighborhood of 200 acres of new vineyard are being set out this season in that valley. Most of the cuttings are the resistant stock, but some are planting the old roots.

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clork Exposition."

Chicks Just Hatched

We ship them everywhere. Pure Bred White Leghorn Chicks from the Best Egg Producers in the United States

CALIFORNIA INCUBATOR CO., MAXWELL, MAY 27, 1906.
Gentlemen—The little chicks arrived in perfect condition. It is very remarkable that 600 little fellows would come so far and keep so long on the way without the loss of a single one, but it is an undisputed fact that such was the case. We are thinking of getting a few more providing we can get them right away. Answer by return mail. Yours truly, J. F. CAMPBELL.

CALIFORNIA INCUBATOR CO., 907 Washington St., Petaluma, Cal.

MORE ABOUT PIGEONS

AMONG the many letters I have received during the past week have been two about pigeons asking questions as to the best breeds for commercial pigeons, squabs for market, and as both ask for an answer in the Cultivator I think we had better take it as our topic today.

About two weeks ago I told of the large pigeon ranch on the Los Angeles river and I also mentioned Mr. Ranson's success with Homer pigeons on his town lots with five hundred pairs of Homers.

Some of the questions asked are:

What kind of pigeons are best for squabs? What kind for market?

What size wire mesh is required for the pens?

What are the best kind of fancy pigeons?

The wire is the two-inch poultry wire, and if you are going into the pigeon business as a business I would urge you to send for bulletin No. 177 as I suggested in my article of April 25th in the Cultivator, as it describes the yards, houses and necessary appliances.

As to the best breed for market Mr. Ranson writes: "The fact that common and mixed breed pigeons are not just as good as Homers for squab breeding is shown in the difference in the price, Homer squabs bringing $3.00 per dozen, whilst common squabs bring $2.00 per dozen." In the U. S. Department of Agriculture Bulletin 177 you will find this recommendation of them: "The best variety of pigeons to keep for squab raising is the straight Homer. These magnificent birds are large and healthy and are good workers, always active and hunting about like the Leghorn fowls; are the best of feeders; are of quiet disposition when properly mated, and their eggs are seldom infertile. For these reasons I consider the straight Homer par excellence among all the pigeon kind, the best for 'squab farming;'" the author of the bulletin is W. E. Rice. He is an extensive and successful pigeon breeder.

In reply to one question there are a number of books for pigeon breeders and fanciers, but I think you would find the magazine called "Pigeons," and edited by Geo. Ewald at Peotone, Ill., would be just what you want and you will find other books advertised in it.

In reply to the question as to how to mark the birds, you might call the first pen "A" and the second "B" and so on. Suppose you have fifty or sixty nests in pen "A"; you should not have more. Each nest has a number. Mark the pair in the first nest No. 1. Put the band on the right leg of the male and on the left leg of the female, let this always be your rule, so that when you see a mated pair you will always know which is the male or the female, and if one dies you can tell which it is and can therefore remate without delay.

Mark the offspring of the pair "A" with a band marked with "A.11" and the second brood "A.12," the next "A.13" and so on, marking all the offspring of "A.1" with a "1." followed by a 3 or 4. The nest next with another old pair mark "2" but pen "A," letting all of their offspring have a "2" on their bands. I think this is about the way Mr. Ranson marks his birds. He is very careful not to inbreed and also to mate properly.

You will find that by banding and knowing each bird individually, it is interesting as well as helpful in the business, for there is a difference in the disposition of pigeons as in people, some are good workers, will have as many as ten pairs in a year whilst others are more lazy and indifferent and will have half the number. You want to breed from the good workers and their offspring, and the only way to keep track of them is by properly banding them.

Mr. Ranson makes his own leg bands with a sheet of aluminum which is easily cut with a pair of scissors; he has dies with the different numbers and letters and has everything so systematized that he has no trouble in keeping a record of his best breeders. A pair of pigeons will live and be good producers for six or seven years, so that when once you have your flock well established and you know each bird, you need only to cull and cull closely and replenish your flocks by taking only the offspring of your best breeders and feeders. There are some parents who feed their young most assiduously and their young grow surprisingly fast, whilst others are poor feeders and those have smaller young birds and are slower in having the next pair, and while the first may have ten pairs of young in a year, the second may have only five or six. It pays to cull and to raise only from the best, for it costs the same to feed a pair that brings in poor results as it does to feed a profitable pair. It takes time, skill and careful work to bring the yield of a flock up to the highest productive point, but it is very interesting and fascinating work.

The trouble with beginners is that they become discouraged and quit if they cannot get the same results in a few months that others are getting who have been breeding, selecting and culling for years. It requires time, patience and intelligent study and then the reward will come.

There are many pigeon raisers in Los Angeles who have from a few hundred to a thousand or more on their back lots that are doing well, and then there is that wonderful and mammoth pigeon ranch of which I wrote, the largest in the world, and yet there is not enough to supply the demand.

I kept pigeons myself for several years and made them pay, and pay well. Then my little grandsons wanted them and I sent them to their home. The first thing the cats got in and there was grief; those that had lost their mates in this raid were remated, then mice came in and the breeding was interrupted and soon there were more males than females and fighting was the order of the day; squabs were killed, eggs broken and finally the red mites came in and the boy's mother set down her foot and the pigeons were disposed of. So I feel as if I know both sides of the ledger.

When it comes to the killing and dressing, the best plan is to make a contract with a restaurant or hotel to deliver so many once or twice a week. You should have a regular

shipping day, and at that time kill all the squabs that are of the proper size. They should be killed before they get so large they will leave the nest. The standard size is eight pounds to the dozen. With properly kept birds, this weight is usually attained in four weeks with Homers. The common kinds take longer.

A little experience will teach you how to kill, pick and dress the squabs quickly. Some markets demand the heads to be kept on; others prefer the heads off—kill according to your market. Bleeding them thoroughly makes the skin and flesh white, which is very desirable.

Fancy Pigeons.

The secretary of the California Pigeon Club, W. E. Foster, writing from a fancier's point of view, says: "The breeding of pigeons in a city can be made to pay and pay well if the party going into the business is a lover of bird life and enjoys the care, attention and study that the pigeon requires."

The late Dr. Westlake once said: "If the bank clerk, the minister, the laborer and all those who toil either by brawn or brain, would take up a hobby like the pigeon fancy and get interested in it, they would receive far more benefit from it than from the medicine prescribed for them by the best doctors in the country." From this point of view, it most certainly would pay. From a money point of view it also pays if properly handled. A person cannot make great sums out of the business in a short time. I cannot tell you what breeds to keep, for there are about eighty varieties; these divided into five subvarieties, each with its admirers, is what constitutes the pigeon world. A fancier having a loft 20x20 feet could breed Pouters, or Maltese Hens, English Carriers or Runts or other of the larger breeds. Another fancier having a smaller space can breed English Owls, Fantails, Nuns, Flying Tumblers or other of the small breeds. Another person with only a little corner might try Turbits, Helmets or Russian Trumpeters. They are handsome and profitable. Still another with only a few square feet of space will find Parlor Tumblers do not need much space, for five feet square and two feet high will accomdate four pair. They sell readily, are little care and afford much amusement.

I feed, as a rule, wheat, kaffir and Egyptian corn, yellow whole Indian corn; occasionally hemp seed and Canada peas; always giving them plenty of good fresh water, both to drink and for bathing. There are very few diseases among pigeons. Grit and rock-salt is needed at all times. The houses should be free from draughts. In starting buy good stock from reliable breeders; prices are from $5 to $15 per pair. Good birds sell readily at all times; poor stock is always a drug on the market.

THE BUFF TURKEY.

The buff turkey is of American origin, having been brought out but a few years ago. Plumage color, pure buff, the wings being a very light shade of buff. Standard weight: Cock, 27 pounds; cockerel, 18 pounds; hen, 18 pounds; pullet, 12 pounds. Disqualifying weights: Cock, less than 12 pounds.

Cleanliness is next to Godliness. This is just as true with henkind as with mankind. Clean perches, clean floors, clean nests and clean hens are what constitutes cleanliness in chickendom.

Perham & Wheeler, R. F. D. No. 123, Lordsburg, Cal.

The Columbian Wyandotte

TWO COLUMBIAN BREEDERS.

The Cultivator takes pleasure in being able to give to its readers two articles on Columbian Wyandottes by two of the foremost coast breeders of this popular variety. Mr. Ironmonger was one of the first, if not the pioneer breeder to take up the Columbian Wyandottes, having imported a trio four or five years ago and has been a continuous breeder of them ever since.

F. J. IRONMONGER
Hollywood, Cal.

ED. M. BURNELL
So. Pasadena, Cal.

Mr. Burnell has bred them for three years, having discarded all other varieties for them. Having bred nine different breeds, he lands after a thorough trial that the Columbians are the best all-purpose fowl. He has about 200 breeders and over 1000 youngsters at this date. This, we believe, is the largest flock on the coast.

THE COLUMBIAN WYANDOTTE.

The wonderful improvement in the quality of the Columbian Wyandottes in the past three or four years was plainly noted in this year's poultry shows both in the East and West. It means that poultrymen(true to name) are taking up the breed and striving hard for supremacy.

But a few years ago the Columbian exhibited at the poultry shows were poor imitations of the breed as it now appears. It was difficult to find a specimen with a clean-cut hackle running to the skin or a clean shank free from stubs; but now after careful selection and mating we were able to see quality in the Columbians (as far as color was concerned) equal to the Light Brahma, and free from leg-feathering. As a guide in modeling the Columbian we have the White Wyandotte, which has been bred for such a time as to develop specimens that rival the Standard illustration for shape. For color requirements we have a still older breed, the grand Light Brahma, the breed that has a great many admirers, especially in the East.

It is hard to find a breeder, a Wyandotte fancier or not, who will disagree with me when I say that the Wyandotte shape is the grandest, plumpest, most graceful and most attractive of any breed described and illustrated in the American Standard of Perfection.

The contrast between the black and white in the Columbians catches the eye quicker that the coloring in any other breed. What is there that will attract more attention on a pretty grass plot, than a flock of snowy-white fowls trimmed in black?

The shape in the majority of Columbians, am pleased to say, equals that of their older relative the Whites; but still many breeders on account of lack of numbers in their yards are induced to use specimens that should go to the pot. It is only by careful and vigilant culling each year that any breeder is able to produce good breeders or show specimens.

In mating up our flock we must not lose sight of the fact that the Columbians are made up from a cross of a White Wyandotte male on a Light Brahma female, so naturally from the Brahma we can expect leg-feathering to crop out occasionally, and for this reason we must not allow any specimens to go into the breeding pens that show any signs of this disqualification unless the specimen is remarkably good in all other points, and then nothing but a little down between the toes should be allowed.

Select males and females as near the standard requirements as possible, for I think the results will be far more gratifying with such matings than from extreme matings such as mating light females with dark males or vice versa as advocated by some breeders.

In mating pens I select a male with the best Wyandotte shape possible to obtain, then look for clean legs (free from feathering or down), then see that his comb is of moderate size and not so broad as to obstruct the fowl's view, it should be well serrated and terminate in a single spike, which conforms and lies close to the arch of the head and neck. The comb on the male has more influence on the young stock, than does that of the female.

The next requirement should be the surface color, especially in the back; which should be white; sorry to say this serious imperfection in males has not been weeded out as it should have been. It is a hard matter, I know, to breed fowls free from brass, you will find it quite common even among White Leghorns. By carefully selecting males and females with white feather shafts instead of yellow, I think this evil will be eliminated.

Next see that the hackle is well defined, not smoky or broken, each feather should have a solid black center edged with a narrow strip of white, a broken hackle or surface nackle should be avoided.

A Pen of Prize Columbian Wyandottes
Owned by Frank J. Ironmonger, Hollywood, Cal.

The primary feathers of the wing should be solid black, or nearly so, having a white edge on the lower web, the secondary feathers should be black with the lower web sufficiently white so as to entirely cover the black in the wing when folded. I should avoid breeding from males or females not carrying the wings well folded as it indicates a weakness, and is bound to crop out some future time.

The main tail and main sickle feathers should be solid black to the skin or as deep as possible, the tail coverts laced with white. A male with some lacing (not ticking) on

the saddle feathers is generally a good feature in producing females. A male with a narrow black stripe in the hackle will produce good cockerels. In selecting females for the pen the same general rule, as to color, can be followed as that of the males. Dark, slaty, undercolor in the back of the females is almost a necessity in order to produce black wings and tails and a strong hackle in the young stock.

From stock filling the standard color requirements in all sections it is more than likely that some of the progeny will—when half grown—show a great deal of black in back, do not kill them until they have entirely lost their chick feathers, for I have found that these same chicks that looked like culls turned out to be my best breeders.

Another feature which is overlooked in both male and female is the color of the eye, which should be a rich colored bay, rather than the glaring pearl found in so many flocks.

My experience with the Light Brahma in the East has given me quite a knowledge of the results in the color of the Columbian Wyandottes, for hardiness and growth I used to think there was nothing to surpass the Brahma, but since taking up the Columbians, I have changed my views entirely; they mature at least two or three months earlier, and are as hardy as it is possible for any fowl to be. From the time the chicks are hatched, they seem to grow like weeds, seldom any sick among the flock. The Brahma blood strengthens any and all weaknesses.

As egg producers the Columbians stand at the front, and before many years have passed Californians will be able to visit many ranches devoted to this breed exclusively where from 500 to 5000 birds can be seen at any time. Their heaviest egg production is during the winter months and bad weather when the lighter breeds would rather stand up under cover and wait for the summer days, to do their work, when eggs are cheap.

I don't intend to advise people what to feed, as that subject appears in almost every paper each month, all I can say is to feed a variety of good wholesome food, no matter how cheap, and results are sure to follow. I think for egg production, rapid growth in young stock and fertile eggs, milk is the purest and most valuable of protein foods, either the skim milk or granulated; as I do not keep a cow I procure the granulated milk by the hundred pounds and keep it before my little chicks as soon as hatched and also my breeders, and am satisfied my wonderful fertility in eggs is due to the liberal use of milk.

I hope this article will be of some benefit to breeders of Columbian Wyandottes, and any questions regarding this beautiful and valuable breed mailed to my address will be cheerfully answered if possible; also likewise any information from breeders will be gratefully received as I, for one, want to see the breed perfected, and am sparing no time or money in producing the best.—Frank J. Ironmonger.

COLUMBIAN WYANDOTTE HISTORY.

The Columbian Wyandotte, the last addition to the family, bids fair to outstrip all other varieties of Wyandottes. We give herewith a brief history of the breed, and a few of their good points.

The Columbian Wyandotte was first introduced, during the Columbian Exposition and from that source the name was derived. They were originated by the Rev. B. M. Briggs, then living in New York state, but now of Moonsocket, R. I. The mating was an accident. The varieties were a White Wyandotte male and a Barred Plymouth Rock female; but by this cross the true feather lacings did not materialize as they should.

Later Mr. Edgar E. McIntosh (now secretary of the National Columbian Wyandotte Club of Hope Valley, R. I.,) becoming interested, used the Light Brahma instead of the Barred Rock with better results and the birds of today it is safe to say are of the Brahma cross.

Two years ago there were 31 birds of this variety entered at the Madison Square Garden show; last year there were 141 entered, and still a larger

DOLLIE
Columbian Wyandotte Pullet
First Pullet, Los Angeles, 1907
Owned by Ed. M. Burnell, South Pasadena, Cal.

entry this season. There was a special offered for the best Wyandotte male, any color. Mr. August D. Arnold of Dellsburg, Pa., won it with a Columbian, which was a great victory for such a new variety. Mr. W. B. Richardson of Rhode Island, has accomplished much for the advancement of these birds in advertising them and exhibiting them at all the large Eastern shows.

Many of the large breeders through the Eastern and the Middle states are taking them up, as they see for them a great future. Never having bred the light Brahma, I quote from a breeder who knows them from A. to Z.

"The Light Brahma has been in this country for half a century. For broilers and roosters they are used to quite a great extent. They are good winter layers of large eggs and are the hardiest fowls we have; being exceptionally free from colds and roup." So it will be seen the Columbian Wyandotte is composed of two of the best varieties of fowls we have.

The National Columbian Wyandotte Club was organized at the New York

JACK
Columbian Wyandotte Cock
Special Prize, Los Angeles, 1907
Owned by Ed. M. Burnell, South Pasadena, Cal.

show in January, 1905, with about twenty members, and I learn that there are already quite a number of members in this club from Southern California points.

For a new variety they breed exceptionally true as to markings, especially in the female. The male birds as yet are inclined to be a little light in neck hackle and tend some to brassiness, but these weak points will soon be bred out, bringing them closer to perfection.

Through the East the demand for stock and eggs far exceeds the supply. Eggs for hatching purposes readily bring from $5 to $20 per setting. From the first prize pen at New York, 1906, 30 eggs were ordered by one party and the price paid was $40.

August D. Arnold's circular says: "The Columbian Wyandotte did not come with a rush or a boom, but came slowly and surely as all great and lasting things come. They have worked their way up to their present high position by honest methods and by their real merits. Their popularity as an all-purpose fowl is but in its infancy. I am of the opinion that we could select one hundred judges and breeders and without a single exception, all would agree the Columbian Wyandotte is the coming fowl. Mr. George E. Howard, editor of the "Feather," Washington, D. C., made the statement at the New York show that the Columbian Wyandotte "would sweep the earth."

For color they should be identical with the Light Brahmas—but should have a rose comb instead of a pea and should have clean, yellow legs. They are good layers of large brown-shelled eggs—are very hardy, and the chicks mature rapidly.—Ed. M. Burnell.

Every breeder of Columbian Wyandottes should not be satisfied until he is a member of the National Columbian Wyandottes Club. This club issues from time to time, valuable information regarding this breed and offers liberal prizes to be competed for at the leading poultry shows by members only. The initation fee is one dollar and dues one dollar annually.

See that the fowls eat the food up clean. Enough for today may be too much for tomorrow. There is more reason why a fowl should have an appetite for an exact quantity every meal than there is that a human being should.

Indian Runner Ducks

Eggs from Pen No. 1, $1.50 per setting, $7.00 per 100. Eggs from Pen No. 2, $1.00 per setting, $5.00 per 100.

What Two Lice Can Do

They can virtually go right down in the poultry keeper's pocket and take the money. If left undisturbed the natural increase is so great that they soon multiply to a swarm that will sap the life of young chicks, breed disease in the pens and ruin profit.

Instant Louse Killer
(Powder or Liquid)
kills lice on poultry, lice on stock, and ticks on sheep. It is harmless to use, and will effectively destroy cabbage worms, slugs on rose bushes, and bugs on cucumber, squash and melon vines. Instant Louse Killer is the original powder louse killer put up in round cans with perforated top. Look for the word "Instant" on the can —then you won't get an imitation.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Turkey Troubles.

You may get tired reading and answering our letters but we surely do not get tired hearing from you. I have a turkey in my flock that is a query to me. She is about one year old; she has never laid. I think she is the largest one I have. Some of the time she is kind of mopy and her head is rather dark. She has a good appetite and has no lice. Her case is beyond my understanding. Will it hurt young turkeys to run on a barley field? How can I tell if my eggs are fertile? How old can eggs be and hatch well? I am handling the Plymouth Rock (Barred) chickens and my early eggs did not hatch very well. I have two cocks with about 38 hens. My hens are large and healthy yet not very fat. They had some lice early in the spring but not enough to stop their laying. The feed I give my flock is wheat twice per day, free range on alfalfa, bone, (green cut) and charcoal, table scraps and plenty of fresh water. Truly yours.—N. L., Oakdale.

It is very rare for turkey hens to be barren, but you evidently have a barren turkey, and if so the only thing you can do is to eat her.

It will not hurt young turkeys or old ones to run on barley or wheat fields; wheat or oats are better than barley as they have not the beard.

You can only tell if eggs are fertile by incubating them for a few days and then looking at them through an egg tester.

Eggs should be as fresh as possible if you want a good strong hatch, but you can keep them two or three weeks, especially if you turn them over every day as the hen does.

There was a good deal of complaint among breeders that their early eggs did not hatch well this year. This depends greatly upon how the fowls got through the moult, the weather conditions and also the condition of the fowls themselves. When eggs are proving infertile more green feed and more meat or animal food should be given and less corn.

It is almost always necessary to give extra green food to insure fertility and also to have no lice. Your feeding is very good.

The rule with B. P. Rocks is eight to ten females with one cockerel but a good vigorous cockerel will fertilize the eggs of ten to fifteen hens; it is, however, too great a strain on his vitality to have a large number and he should have extra food or be fed separately every day.—Mrs. A. B.

Turkeys.

I hope you will kindly give me some information in regard to the trouble with turkeys. I have one that sits around and will not eat. I gave her one dose of calomel and followed it with Carter's pills one for three days, and fed her by putting food in her mouth two or three times a day for over two or three weeks, she would seem a little better but did not eat. Yesterday morning I gave her a dose of anilene and this morning she was dead. I opened her and found her full of a yellowish water and a yellow substance, two or three eggs partly formed. The liver was spotted with yellow spots all over. Please tell me what to do if any more get sick?

Your turkey died of liver complaint. I do not know whether it was the infectious kind called "black head" from the combs turning black or just common liver trouble, because you tell me so few of the symptoms and nothing about how you feed. The best way to cure the disease is to prevent it by keeping the turkeys healthy, giving them plenty of green food, clean water and animal food and as much free range as possible. When the disease has once commenced it is difficult to cure; however, liver pills alternating with quinine is the best remedy that I know.—Mrs. A. B.

Weevil in Hay and Grain.

Will you please give me a remedy for weevil in hay and grain? Subscriber, Orange.

Close the grain box with a little bisulphide of carbon in a dish setting on top of the grain. A half pint in a box three feet high and wide and six feet long will do the work. When they are in the hay, it is a difficult proposition. When your barn is empty sprinkle a gallon or two of the liquid on the inside on the walls and ground or floor. We will not say that this will kill them all in the hay but it may be worth the trial. Bisulphide of carbon is very inflammable and will explode at the "sound of a light," so don't use a lantern or allow anybody near it if you do this. You will have to do it quickly and get out of the building or it will treat you just like the bugs you are after.

Another good remedy is gypsum. Sprinkle it on the top of the grain in the box and it will soon smother the weevil. Perhaps this would work on your hay. It is harmless to the stock and is tasteless. It seems to act as insect powder, and while it does the work in grain, it is not so quick as bisulphide of carbon.—J. W. M.

Lemon Tree Nursery.

Will you please state in the columns of the Cultivator how to proceed to raise a nursery of young lemon trees. Also what is considered the best variety?

Kindly state the proper periods of planting seed, of budding or grafting, and time of permanent planting in orchard.

Thanking you for the past favors and valuable information received, I wish you success.—F. M. M., Ventura.

Remove all lumps or gravel from the soil to a depth of 18 inches, mixing some well-rotted stable manure with the soil to within five or six inches of the top of the soil of the completed seedbed.

The seed should be planted now in rows about five or six inches apart and as thick in the row as possible without having them too deep. That is, place the seeds in the trenches or small depressions made for them, so that they will just touch each other. These trenches should be about twice as deep as the seeds are thick.

Cover the seed with earth so that it will be level with the surface when pressed down with the foot. Cover with about half an inch of sand. Keep the seedbed shaded as a lath house or a piece of single burlap will do, till the plants are up several inches. In the meantime accustom the young plants to the sunlight till they can stand the full sun for the whole day. Keep the seedbed moist all the time clear to the surface. It is necessary

to settle the soil in the bed before planting with water and then smooth evenly, tramp it down and smooth again.

Sweet orange is mostly used for lemon stock, though pomelo and sour stock are good and may be better. This has not been definitely settled yet.

Eureka is the favorite lemon. Lisbon and Villa Franca are good. Lisbon is a better shipper than the latter, but has thorns, which quality is slightly objectionable.

Plant the trees from the nursery when one-year old. Let them grow all that summer, bud in the fall, remove the tops in the spring from those in which the buds have taken and tie the sprouted buds to stakes after they get up 10 inches or a foot. Allow them to grow one or two years in the nursery before planting in the orchard. Plant any time after the last of April till the middle of July. Some plant later in warm locations.—J. W. M.

Shot-Hole Fungus.

Will you please give me all the information you can "through the Cultivator," regarding the shot-hole fungus?

My orchard has been attacked by the pest and I wish to exterminate them.

If possible tell me the season in which I might get at them with spray, if spraying will kill them, or by what other means I may get the better of them.

My prune orchard is in black adobe land about twenty-four inches to hard-pan, wet in winter and never very far to moist dirt.

The trees are about fourteen years old and on the Maribolan root.—C. P., Santa Clara.

Spray your trees with Bordeaux mixture early in the winter. Lime sulphur and salt spray will also do the work, but it is more expensive and troublesome. If you have scale on your trees, the latter spray is the one to use as it will kill both the shot-hole fungus and scale.—J. W. M.

Bugs and Plums.

Will you kindly describe the "Sow Bug." Is it sometimes known as "Silver Bug?"

We have a Satsuma plum tree 5 years old that has never borne a plum although it blooms very freely. It makes a very rampart growth. Can you suggest what treatment it should receive.

A reply to the above enquiries through the Cultivator would greatly oblige.—A Subscriber, Claremont.

A good illustration of a "Sow Bug" may be seen, with a little change, in some reference book such as a cyclopedia of geology. If you can find an illustration of a trilobite, he will do with a little smoothing off of the corners. Never heard it called "Silver Bug;" a common name is wood louse.

Your Satsuma plum trees will bear when they get to be a little older. They are too vigorous to do much bearing. When they get past that stage they will get down to business and suprise you.—J. W. M.

Alfalfa in Orchard.

Will alfalfa do any damage to an apricot crop to sow it between the trees?—A Subscriber, Campbell.

Alfalfa will do your trees good if you have water enough for both.

Teat Trouble.

I have a young heifer that will be fresh in June that has a hard substance about her teats which apparently seems to be a wart; it is about the size of an ordinary marble. Can you give me a remedy that will remove same and oblige. A Subscriber.

If this animal is of sufficient value have the veterinarian operate as there is danger of obliterating the milk duct when ordinary people try to handle a lump as large as this one.

Legal Queries

Answered by L. M. FALL, Esq.
204 Frost Bldg., Los Angeles, Cal.

This department is edited by a practicing lawyer, who has had years of experience at the bar. He will give accurate and reliable answers to all legal questions when they are of sufficient importance to be of practical interest to any considerable number of our readers.—Ed.

Private Roadway.

My farm lies on the main road. My neighbor's farm lies just behind mine away from the road. For ten years he has been accustomed to go through my land to reach the road. Failing to close the gates, between my land and the road, I have ordered him to cease crossing my land. He now demands the use of the pass-way on the ground that long usage has given him that right. As he has used the strip, without any contract so to do, am I under any obligations to permit him to continue to use it? Have I the right to nail up the gates on his line and my own and refuse him admission to my ground? Subscriber, Lankershim.

If your neighbor alone has used this road it is by mere license and he does not obtain a permanent right thereto. In which event you would have a right to nail up the gates.

Who is Owner?

I bought a tract of land on contract. Wish to make improvements on it. In case I fail to make payments as provided in the contract and the land reverts, can I recover for the improvements? A lawyer told me I could recover the money actually expended for improvements if the seller expressed a desire for me to make them.—Mrs. B. C. E., Redding.

Unless it is stipulated in the contract to the contrary, the improvements become a part of the realty and cannot be removed without the consent of the owner.

Overflowing Well.

What is the best course to pursue when a neighbor's well overflows so that it renders adjoining property impossible to work? W. L. S., Nordhoff.

Your neighbor is liable for the amount of damages sustained by you. You might build a levee along your line and thus turn the water from your land.

Dog Killed.

A neighbor came into my yard and shot a valuable dog out of spite. The dog had not injured any of his property that I know of. Can I recover the value of the dog? Please answer.—W. W. C., Oxnard.

Yes, and probably exemplary damages.

HAVE YOU GOT YOURS.

Have you received the splendid free picture of the 1907 Girl? After much trouble and expense, the Sharples Separator Co. succeeded beyond their hopes in reproducing from life, in the softest and daintiest colors, the sweetest dairy maid ever offered by any cream separator company as a free picture suitable for framing and placing in any home.

Send at once to the Sharples Separator Co., West Chester, Pa., the names and addresses of five farmers who keep cows but have no Tubular Cream Separator, and the Sharples Separator Co. will mail to you, in return, the picture of the 1907 Girl, free from printing and large enough for framing. Write the names plainly. Give your own name and address clearly. You must mention the name of this paper to get the picture.

It has been amply demonstrated that Imperial valley is the ideal country for turkeys, and the shipments last year for the Thanksgiving and Christmas holiday trade ran into the thousands of dollars.

In the line of sorghums, 380 varieties have been received at the Chico gardens, but of these only twenty-five have been used, so radical are the selections.

Don't Feed

the little chicks anything for the first twenty-four hours. Then feed them dry.

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seeds, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keep it, and will not get it, send $3.35 for 100 lbs., freight prepaid by us to any point in California.

Are your fowls a little off—don't you want to tone them up?

West Coast Poultry Tonic

will do it sure. It is one of the greatest cures for ROUP and all kinds of colds.

Hen Fruit Pays—if you want more, feed

Egg-More

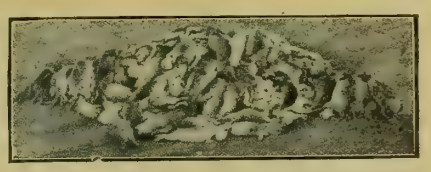
That highly nitrogenous poultry food, rich in protein, to keep the poultry in good health, and enable the hens to convert the surplus aliment into eggs. Just the right addition to a good grain ration.

West Coast Lice Killer and Killamite (powder)

are most effective pest destroyers. Nearly all the diseases of poultry may be attributed to lice and mites. Don't let them get the best of you. Get the best of them. And did you know that Killamite is just as good for killing plant insects without harm to the plant. Testimonials of public gardeners and others. Try it on your roses. 50c sifting cans by mail if your dealer won't get it for you.

West Coast Poultry Foods and Remedies

are the best made and, quality considered, the cheapest. If your dealer doesn't sell them, send to us. Booklet free. Send us names of 12 persons keeping poultry and we will send you free "The Poultry Manual" by those high authorities F. L. Sewell and Ida E. Tilson, profusely illustrated.



This is a photo of 201 Gophers killed in one day on a 10-acre field with one bottle of

BILLE'S GOPHER POISON

Not one of the ordinary poisons, but in a class by itself. Endorsed by Agricultural colleges and Experiment Stations. Has had greatest success in the Middle West. The secret being that it is most attractive to gophers, squirrels, etc., and sure death to them. It gives the grain a glossy coating, retaining the poison for weeks. Hundreds also die in their holes by eating it there. We have bought the patent right for this section and are selling at the eastern price, lower than the ingredients can be bought at a drug store. Money refunded if not as represented—so printed on the bottle. If your dealer does not keep it sent $2.50 for two bottles, express prepaid by us—not less than two bottles.

Confident that a trial will prove beyond question that the best condition powder made is

West Coast Stock Food

We will send to new customers one 25-lb.

$3.00 PAIL FOR $2.00

or one 50-lb. $5.75 double sacks for $3.50, and will prepay the freight to any point west of the Rockies. Not more than 50 lbs. to each one, and we reserve the right to withdraw this offer without further notice. No cheap premiums, no gaudily colored pictures, but a legitimate business offer to induce a trial, hoping to add many steady customers. We are charging up the difference to our advertising account, feeling sure that a trial of the goods is the very best advertising.

No strings to this offer. Just send us your name, the freight station to whch you want the goods shipped, mention this paper, and we will do the rest. Send money order or check with your order, and if every thing is not exactly as represented your money will be refunded. The First National Bank of this city, or Bradstreet's Agency, or any leading firm, can inform you as to our reliability. WEST COAST STOCK FOOD has for many years been a standard condition powder in this section. See our full page adv. in the March 7th and 28th issues of this paper or send for circular with testimonials.

UNIVERSAL HOPE.

The humble man out yonder who is
working in the ditch
Has the hope within him hidden that
some day he may be rich;
He has done no wise investing, he has
earned no man's regard;
He has wasted precious moments
when he should have studied
hard;
But, forgetting all the seasons that
so foolishly were spent,
He keeps longing he may profit
through some lucky accident.
The faded maiden, stitching as the
mirthless moments pass,
When the long day's work is ended
stands with hope before her
glass;
Youth and beauty she may never
claim again beneath the skies,
There are wrinkles radiating from her
dulled and weary eyes;
But within her bosom always an up-
lifting hope is pent;
He and she may meet tomorrow
through some lucky accident.
You have sought to win such honors
as the world gives to the great,
But your efforts have been fruitless;
still you labor and you wait;
I have builded Spanish castles; I
have longed to win applause
For heroic demonstrations in some
splendid, thrilling cause;
And we plod along, still hoping that
the grim fates may relent,
Each expectant and each waiting for
the lucky accident

—S. E. Kiser.

A SERIOUS TRESSPASS.

"KEEP STRAIGHT on till you come to the coast. Farther on you will pass through a defile with towering cliffs on either side. Do not on any account ascend the rocks on the right, for up therre is Livadia, the summer palace of the Czar."

The words were spoken to Frank Huxford of Chicago, globe trotter, mountain climber, grain operator, club man, horse jockey, anything, everything that a versatile American is capable of taking up, though how he managed to gratify so many tastes in one lifetime no one could find out. He had asked the way of a man who had answered in the Russian tongue, but Huxford understood never a word, so he proceeded in the direction the man pointed, trusting to luck to find his way. He soon struck a dense wood, from which he emerged in the defile mentioned by the man of whom he had inquired. On either side were cliffs, and his climbing instinct led him to attack an almost perpendicular ascent on his right. It looked plain enough from below, but on the route he was in the midst of dense scrubby trees and could neither see nor be seen by any one.

He emerged at last on a plateau, where he stood wiping the prespiration from his face and enjoying the view. Presently he lowered his eyes, and at the foot of the cliff where a section of the road was visible he saw a soldier leaning lazily on his gun. On another exposed section he saw several sentinels posted at short distances from one another.

Walking inward from the edge of the cliff, he came to a finely finished road and in another moment heard the patter of a pony's feet on the hard surface, and a phaeton containing a young woman and two little girls came round a point of rocks. The lady was driving, and, seeing Huxford, reined in the pony and asked him something in Russian which he did not understand. He took off his hat and made a bow in true American fashion and replied in English, for, his jaws not having been fashioned in infancy to utter bone cracking sounds, he had not learned the Russian lauguage. The young woman burst into a laugh and said in English, with a British accent:

"I asked you whether you have seen the Count Ehminoff go by here."

"I have seen no one go by here. I have just climbed up from below."

The lady's face grew grave. "Do you mean," she said, "that you have entered here except by the gateway?"

"I came from the road down there."

The lady paled. "But how did you pass the guard?"

"That accounts for a chain of soldiers I saw below. I didn't know there was a guard."

"Great heavens! You are in the Czar's grounds. How reckless my countrymen are."

"I'm not your countryman unless you are an American."

"Americans are just as foolish as our Englishmen. Do you know that you are in a frightful position?"

"Oh, I've climbed the Matterhorn. This is nothing. Do you suppose I can't get down where I have come up?"

"You passed the guard by one chance in a hundred. You can't expect to win that chance again."

"I will apologize to his majesty for trespassing."

"You will not see his majesty. You will be arrested and treated as a would-be assassin."

Both paused in the conversation, and both did a great deal of thinking in a very short space of time, at the end of which the lady said:

"Get in here quick."

The children were on the back seat, and Huxford got up in the front beside the lady. He had scarcely done so when there was a clatter of horses' hoofs coming, and a gentleman on horseback, followed by a groom, met them. Both he and the lady drew rein.

"Ah, count," she said in Russian, "I feared we had lost you. The children would have been greatly disappointed."

"I would join you, but I see you are full," replied the count, looking inquiringly at Huxford.

"This is my cousin, just from England, the Hon. Hubert Granger." Then in English she introduced Huxford to the count.

What further she said was in Russian and Huxford did not know what it was until he saw the count dismount and by pantomine offer him his horse. The lady told Huxford that she had expressed his wish to visit the opposite cliffs, and the count had offered his horse, with his groom, to point the way. Huxford, having alighted, made an American bow to the count, a French bow that he had learned in Paris, to the lady, and mounted the count's steed. Then, having made two or three more bows of different nationalities, he galloped away.

At the gateway the guard scrutinized "the Hon. Mr. Granger," but, seeing Count Ehminoff's groom following him, said nothing. Once well on his way, he wrote a pencil note on a blank page of a letter to "his cousin," stating that he had received a summons to England and must go without a moment's delay. This he gave to the groom and dismounting, pointed to Livadia. Then putting the reins of his horse in the groom's hands, he walked away.

Huxford failed to discover who was his preserver. One clew indicated that she was the governess of Count Ehminoff's children. Another, better supported, made it appear that she was a relative of the Czarina and a member of the English royal family.

WENDELL C. M'LAIN.

HOW SHE SECURED HER POSITION.

She was riding in to the city on the morning train in search of a position as stenographer. Having seen the large, florid man in the seat in front of her cut an advertisement from his newspaper and put it away in his pocketbook, she was just curious enough to look up the corresponding place in her own paper. Finding there an advertisement for a stenographer, she noted down the address and thanked her feminine curiosity.

She then turned back to her pencil and notebook. It seemed as if, practise as she might, she never could keep her speed up to one hundred words a minute. She tried copying from the newspaper, but the motion of the car made the words dance before her eyes until they hurt her. She tried making up sentences as she went along, and failed. Finally she resorted to talking down the incessant chatter of two women behind her, but their talk was often drowned in the disturbances of a number of young people still farther back, who were riotously noisy.

The young lady struggles with a tirade on the servant-girl problem, timing herself by the distance between stations—two minutes from Sherwood to Sherwood Corners; could she do two hundred words? As her hand dashed madly over the page, a large wad of newspaper flew past her and struck the florid man in the neck. The laughter behind subsided into dismayed giggles.

Slowly the large man turned his injured neck. He was redder than ever as he started to speak. The words fell from his lips, hot but distinct, swiftly but smoothly. He was telling the boisterous young people seven seats back just what he thought of them.

The young woman with the pencil saw her chance and took it. Here was glorious dictation. Her pencil flew. The speech lasted a minute and a half, and was cut short then only by the arrival of the train at the terminal. The stenographer slapped her book shut with a comfortable feeling of having done even better than a hundred words per minute, and set off in search of her position.

When she arrived at the address she had noted down, she was ushered into a private office where sat the man of the speech. She stammered a little until she saw that he did not recognize her. His mind had been full of bigger things. Then she smilingly told him her errand.

"Do you think you can take my dictation?" he said, frowning.

"Yes, sir."

"What makes you think so? I talk very fast."

"But very distinctly, sir." She produced her notebook and laid it open before him. "Here's a sample." She began to read her notes.

LEE'S LICE KILLER
Henry Albers Co. 315 South Main Street Los Angeles

His jaw dropped. There was his masterpiece of the train, complete and unabridged. It really sounded very well, so full of fire.

When she finished he looked at her sharply. His face was very red, but his eye twinkled.

"The job's yours," he said, in a subdued voice.—The Youth's Companion.

CANNING PEAS.

All varieties can be canned, but it hardly pays to do any but the best. Fermentation sets up readily in uncooked peas so that it is hardly safe to can any that have been picked over ten hours. The peas are shelled carefully and sorted as to size. If it is desired to have them remain green like the French peas, they are mordanted with sulphate of copper. To ten gallons of water add one ounce of sulphate of copper and five ounces of salt. When the water boils put in the peas and after five minutes drain of the water and fill the kettle with cold water to chill the peas as quickly as possible.

The American way is to simply use the salt in the water, this makes a yellow looking pea. The salt solution is used first as a cleanser from bacterial taints and must be thrown away as it will spoil the peas if used as brine on them. Fill the can or jars with the peas carefully. Use either of the following brines on the peas:

One pint of salt to six gallons of water, boil it up hard and skim, it can be used hot or cold over the peas in the cans. The other is the sweet brine, I like it best myself. One pound of sugar, one pound of salt to six gallons of water, cut up a small onion and add a head of lettuce; cook well and strain out the vegetables. Put the peas into the cans, fill up with the brine and solder all except the blow hole, or if in glass do not tighten the lids down. Add to the water in the kettle in which they are boiled, a pint of salt to each gallon of water, this gives a higher heat than plain water. Pints require 7 minutes cooking, quarts 10; remove from the kettle, solder or tighen up the jars, and then boil the pints ten minutes more, the quarts fifteen, in plain unsalted water. Take out, stand upside down until the next morning and if any are not tight they will have leaked. If in glass jars wrap them in paper to keep off the light, as it will fade the color out rapidly. A pinch or two of baking soda will aid if the peas are soft and show any tendency to discolor the water they are mordanted in.—Minna E. Sherman.

Cauliflower.

This vegetable a few years ago was a luxury; it is now cultivated by nearly all market gardeners, and is within the means of all housekeepers. It is a most delicious vegetable, when properly cooked, and vile when improperly cooked, which generally means when overcooked.

Remove all the large green leaves and the greater part of the stalk. Put the head down in a pan of cold water which contains to each quart a teaspoonful of salt and a teaspoonful of vinegar. Let it soak in this water an hour or more. This is to draw out worms, if any should be hidden in the vegetable. When ready to cook the cauliflower put it into a large stewpan, stem end down, and cover generously with boiling water. Add a tablespoonful of salt and cook with the cover of the saucepan partially off, boiling gently all the time. A large, compact head will require a full half hour, small heads from twenty to twenty-five minute. If the flowers are loose the heat penetrates to all parts quickly. When compact a little extra time should be allowed for the cooking, but the time must never exceed the half hour. The cauliflower begins to deteriorate the moment it begins to be overcooked. Overcooking, which is very common, can be told by the strong flavor and dark colo. It makes the vegetable not only unpleasant to the eye and palate, but indigestible also. If this vegetable must be kept warm for any length of time, cover the dish with a piece of cheese-cloth. in hotels and restaurants. It is better to blanch it, chill with cold water, and then heat in salted boiling water

DOES MAN WOO OR IS IT WOMAN?

Professor E. A. Ross of Wisconsin university has been talking most unpolitely. Man is not the wooer but the pursued in the human family, he says.

"In all lower animal families it is the male that is decorated and adorned. But when it comes to the human family there is a change. The females are the ones decorated and adorned and they decorate and adorn themselves to please the males. They dress to catch the eye of men because it is upon the men they must depend for a living. By dressing and adorning themselves, making themselves beautiful in the eyes of the men, they are able to secure a home and livelihood.

"Men are the burden bearers. They must do hard work. They have no time for decorating themselves. Women have great leisure and are enabled to attend to display. And by the display which the women are enabled to make their position in the world is fixed. The woman with the ability to make the most display stands highest.

"The woman who has many diamonds and rich clothing, proclaims to the world the fact of her husband's prowess in the financial game."

CARE OF WOUNDS.

If your horse picks up a nail in his hoof, tear away the horn until the blood starts. Then wash it thoroughly in a solution of bichloride of mercury at the rate of one part to 500 parts of water. Never close up a wound of this kind, but place absorbent cotton over it and then bandage with a thick cloth coated with tar. The essential thing is to keep out all dirt and allow the wound to drain.

BACK TO THE FARM.

One of the distinct features of the age is the tendency to return to agriculture. Where a few years ago the farmer's boys were rushing to the cities to crowd the professions, there is now a decided move in the other direction.

The natural reaction that must always follow a movement so radical in some measure accounts for the disposition to return to the soil for a livelihood, but there is more.

The agriculturist has become a professional man. The college and the university have added a special course for his benefit, and given him a degree.

He is a botanist and a chemist, and science has taught him to take in the jaded and worn-out farm, and with intelligence cause it to blossom like the rose.

The dispiriting labor which bent the forms of the elders and sent the lads scurrying cityward has been lightened by devices that better accomplish the end sought.

The long hours are shortened, and the farmer finds time to indulge in the enjoyment of life. This new condition, added to the fascination of independence, has turned many men from other professions toward the country.

The Perfection Generator The Best Individual Gas Plant Known.

So Our Users Say. Listen:

"BEST light ON EARTH."
"Could NOT think of GOING BACK to common gas or electricity"
"MOST PERFECT artificial light known"
"Only light that makes night reading COMFORTABLE and SAFE"
"Very BEST light we have EVER SEEN"

MISCELLANEOUS.

FOR EXCHANGE—1 FINE FEED CUTTER, value $15, for fancy poultry or pigeons. Also Express wagon for laying hens (large breeds). H. L. BAUER, 737 S. Spring St.

METHOD OF IRRIGATING.

Most irrigating is done by one of two methods—through furrows, or by flooding. The furrows may be permanent or temporary. Plants such as strawberries and small vegetables that require the frequent application of small amounts of water are by most growers irrigated through furrows that are more or less permanent. Some farmers break up by cultivation the crust that forms on the surface, while others simply hoe from the furrows and the intervening ridges the weeds that grow there. This method of irrigation should be resorted to only in the case of such crops and under such climatic conditions as make it difficult to irrigate by any other method.

In Santa Clara and Alameda counties the prune crop will be about 50 per cent. of a full crop, for in many sections the trees were late in blooming. Apricots will be short, although some places report a good prospect for canning varieties. Similar reports come from Contra Costa.

There is a great divergence of opinion regarding the Vaca valley pear crops owing to losses which may result from dropping. Some say the outlook does not promise over a third of a crop; while others count on nearly a full crop with the exception of loss occasioned by blight.

AUCTION

31 MILK COWS
1 JERSEY BULL

Thursday May 16

At 10 a. m.

On my ranch 1 mile East of
CYPRESS

on Santa Ana Electric line, 5½ miles west of Anaheim. Take Santa Ana Electric cars to Cypress; teams in waiting.

31 head of first-class dairy cows, Jerseys, Durhams and Holsteins, all heavy milkers, young and in good condition; some fresh, others coming in soon. In fact, this is an extra choice herd of dairy cows; 1 registered Jersey bull.

On account of other business I am retiring from the dairy business, and am closing out my entire herd. Every animal will positively be sold to the highest bidder without reserve or limit.

The Produce Markets

Los Angeles Markets

LOS ANGELES, May 9, 1907.

Business in the produce market is still flourishing and dealers are doing a large volume of trading. Many estimate the demand for produce occasioned by the large number of visitors in the city is even greater than during the holidays.

Butter.

Butter is still very firm. Dealers are having a hard time meeting the big orders, notwithstanding a heavy shipment yesterday which arrived by boat from the north.

Valley Creamery	47½
Coast fy,	45
Cooking	20

Cheese

Cheese is slightly firmer than it has been for several weeks, but the supply is still very heavy and the general tone of the market is weak.

Cal. Young American, per lb	19
California Anchor	18
Cal 3-lb. hand	20
Northern, fresh	15½
Domestic Swiss	22
Imported Swiss	30

Eggs and Poultry

Poultry dealers are probably having the most difficulty in supplying orders and owing to the inadequate supply prices have advanced 2 cents per pound. Orders were sent in by the largest hotels and restaurants several days before the Fiesta opened but the wholesalers have been unable to obtain a sufficient supply from the country and consequently are scaling these orders.

The demand for eggs this morning was strong but receipts were large, and, contrary to expectations, the price was not advanced on the Exchange. It was the opinion of the best posted dealers that prices would go higher tomorrow.

Eggs, local, per doz	21½
Northern Candled	19
Fresh Eastern	18

The following are average prices which dealers pay to producers for live weight:

Hens, per lb.	16
Young Roosters, per lb	18

Read what this man says about Columbus Engines:

Greenleaf-Compton Company, Tropico, Cal., 4-3-07.
121 So. Los Angeles St., Los Angeles, Cal.

Gentlemen—For about four years, I have used a Columbus engine of ten (10) horse power; which has been running a 3½ Vertical pump and pumping about 35 inches water with a 90 foot lift, and when the time came to buy a new pumping plant for my ranch near Anaheim where we we shall need water for about 200 acres, I decided to have a 60-horse Columbus engine installed, and placed the order with you because I expect to have a pumping plant that cannot be excelled.

Respectfully, E. B. BARY.

This 10-horse engine is pulling 13½ horse power. We are installing a 60-horse plant for Mr. Bary, 3½ miles north of Anaheim. Come in and let us demonstrate the simplicity of Columbus Engines.

Injurious Results of Immature Breeding

THERE HAS BEEN a tendency shown in the last few years, among breeders, to attempt to breed heifers before they have become mature. Especially has it been shown to be the case with many dairymen; so anxious have they been to get their herds on to a paying basis that they have seriously injured their heifers by making mothers of them at too early an age. The practice of this immature breeding has been so extensive, and is so extensive today, that in many localities mature cows in the dairy breeds cannot be found. The result is that we have been producing in California a smaller type of the dairy cow, and, consequently, a less effective cow than is to be found, in general, among the herds of the Eastern or Middle West dairymen.

The theory upon which these dairymen have based their conclusions has been that the earlier a heifer is made to produce, the sooner she brings financial returns for her keep, but it has been found by practical demonstration that too early breeding produces an immature cow, immature as to size, and naturally inefficient in milking qualities. The most successful herdsmen, in the Middle West, are those who do not undertake to breed their heifers before they are twenty-four months old. They, therefore, obtain a larger cow, with larger bone and greater vigor, and naturally get better calves and more satisfactory milking results than those who have made it a rule to breed at eighteen months.

It was a notable fact that the twenty-five Jersey cows entered in the dairy cow demonstration, at St. Louis, in 1904, were large cows. The results obtained in that test were superior to any results obtained from cows that were smaller in size and less in weight.

While it is clearly apparent that immature breeding reduces the size of dairy cattle, it is contended by some that, necessarily, constitutional vigor does not always accompany this loss of size, but experienced dairymen are reaching the conclusion, at this age, that the best and most continuous results are obtained from the breeding of mature heifers.

In Northern and Central California the subject of stock improvement is attracting more attention, as we have said, than at any previous period in the history of dairying. Farmers in the Middle States are used to large cows in the herd, both for beef and dairying purposes, and are loth to be convinced that a small cow will bring the same results that a large one will, hence we read that breeders of Holsteins and Durhams are finding a market for their bulls among the dairymen of Northern California. It is quite likely, as the country settles with Eastern farmers we shall have a bigger breed of dairy cattle, but the Jersey has been the popular cow in California and will continue to be popular, if bred up to her possibilities. The purely dairy operator is looking for the cow that will give him the best butter fat return, and he will find the Jersey unsurpassed if she is bred true and to strictly thoroughbred bulls of best type.

The same principle will apply to raising beef cattle. The beef producer is after size and bone. The above illustration refers more to beef than dairy stock; but what will apply to one will also apply to the other if size is an element to be considered.

A Plan for the Improvement of Cattle

Extracts from an Exhaustive Report on Experiments and Observations on Too Early Breeding and Inbreeding of Cattle

By E. S. Shaw, of the Live Stock Experiment Station, Michigan

IN PRESENTING the following article from Professor Shaw, it will be noticed that the trend of his discussion is for a better grade of dairy and beef cattle. It is along the line of argument that the Cultivator has followed for several years. Breeders are beginning to realize the importance of a better standard class of cattle, not only for the product of beef, but for the dairy interest as well. We cannot hope to reach a higher degree of excellence in our animal industry on the Pacific coast, until we realize the importance of placing at the head of our herds thoroughbred bulls of whatever type it is desired to promote. Examples are numerous of successful dairying where the industry has been promoted from high-grade stock.

In the counties north of the Techachapi especially, dairymen and ranchers in general, have been paying more attention of late to the dairy bull than has heretofore been the case. The result is, that the dairies in Northern California and Central California are in better condition than they are in Southern California. It will be a glad day for California when the same interest is manifest in breeding to the highest point possible, our dairy and beef cattle, as is manifest in the sections of the Middle West.

Principles.

The presentation of this publication, at the present time, is designed to serve a two-fold purpose. First, it is intended to be preliminary to reports of animal breeding experiments of an important practical nature either now in progress at this institution, or about to be taken up. Some of this work has been under way for more than eighteen months, and many more months and several years, even, must needs elapse before other phases can be completed and reported. These investigations are being pursued with the idea of securing more definite data relating to some of the problems hereinafter discussed. In the second place, it is hoped that the following discussion may lead to the adoption of better methods in some of the commoner practices of animal-breeding, the principles of which are frequently grossly violated, quite as often through carelessness and indifference as through a lack of knowledge of them.

For the purpose of the discussion that is to follow, we shall divide the producers of cattle into two classes. First, there is that class comprising the small minority engaged largely in the production of pedigreed animals to be offered for sale for purposes of improvement; we have no criticism or suggestion to offer this class. They are by far too few and do not receive the support and encouragement their efforts deserve. There are a few who undoubtedly own pure-bred animals, but have not been keeping the registration up. On the other hand the list of owners of registered animals must include some who own but a single recorded animal, namely, a bull. The fact that these men own recorded stock is evidence enough that they are interested in live-stock improvement, and are familiar with, and are practicing good methods of live-stock breeding.

The second class, comprising by far the great majority, is the one in whose hands the inferior stocks are to be found. Because this last class comprises such an overwhelming majority of stock-owners, and because it produces nearly all the animals and animal products marketed, its influence in determining the character and reputation of Michigan meat and milk products is very far reaching. It is in the hands of some of this class that the scrub and animal of badly mixed breeding are to be found. After the few breeders of pure-bred animals have expended large sums of money for good foundation stocks, and offered good young pure-bred males at moderate prices, it cannot be denied that they are extremely slow of sale. The ordinary producer of meats and milk (not breeder) seems determined not to pay more than about meat prices for males to infuse improved blood in his herd, and the breeder can not make a living producing them at such prices. Failing to secure improved males at these low prices, many producers fall back on the grade or even the scrub, and frequently combine with this inbreeding, especially where the males are chosen within the herd. The greatest and most pressing needs of to-day in live-stock improvement, are more breeders, more good males, and more men willing to pay remunerative prices for them, and cease admixing blood, and using grade and scrub sires.

We may expect, after a few top-crosses in upgrading, that the progeny will resemble the type of the sires used in improvement quite closely, both as to form and general characteristics; in fact, so much so that the high grade may eventually equal the pure blood improver from a standpoint of utility in meat or milk-making, as the

Deciduous Fruit Culture

By J. W. MILLS

REPORT ON COVER CROPS.

THE following is a report of investigation carried on by Mr. C. S. Vaile of Claremont and made before the Claremont Farmers' Club, and is more largely of conditions in that neighborhood:

The past year has seen a greatly increased acreage sown to cover crops, chiefly peas and vetches.

This general use has come about largely through the urgent advocacy of cover crops before our clubs by some of our more alert orchardists.

The fruits of experience are the test of value. So it seemed wise for future guidance to gather the opinions of those who are experimenting with such crops. The inquiry paid special attention: To the time and method of planting; the after-treatment of the crop and soil; also an inquiry into the respective values of different cover crops and the place they hold in the system of orchard fertilization.

Local Conditions.

The study was largely local, but included a few reports, by way of comparison, from large orchardists in other districts, where the use of such crops has been more general. Their crops chiefly consist of peas and vetches, though in the less dry coast districts fenugrek is found to be satisfactory, while burr and sweet clover and the lupin seem to grow in favor. Many who planted peas last year have this year sown vetches, fully one-half the acreage planted being this kind.

Many sowed upon their faith on others' say-so, while others only experimented with a few acres. A few mixed the vetch with the peas, while others cross-sowed with burr clover.

Vetches First.

The preference seems to be for vetches. The reasons assigned: "They cover the ground better, root deeper, form a greater mass or roots, seem more hardy, will better stand rough treatment during fruit gathering, need less water, plow under better and more easily, and, while needing longer time to decay, they probably supply more humus, possessing the finer fiber." The results of mixing vetches and peas and at times barley were very satisfactory. The barley prevents the ground from washing by the early rains and later forms a support which aids the other crops in their growth. Some growers declined to express a preference until they could note comparative results. One large rancher used peas on the level clean land, but sows vetches on hilly, foul land, for they better prevent washing of soil and keep down other growths.

Experiment a Little.

It is suggested that more orchardists might emulate the example of some of those having charge of large orchards and experiment for themselves with different kinds of cover crops. The time and methods of planting varied somewhat, though this difference came more from circumstances than from opposing views. The crops were sown from the latter part of September on through October and November, but chiefly in October. The earlier sowing has the preference, provided early rains or irrigation permits. Even should the ground continue dry, the vetch seed and clover, at least, will remain dormant ready for spring when rains do come.

How to Plant.

The method of planting varies little. Hard ground should be plowed, then thoroughly irrigated and cultivated, the seed drilled in or broad-casted, better the latter in old orchards, 40 to 60 pounds of vetch to the acre, then the ground furrowed shallow, for future irrigation as needed.

These cover crops were grown in all sorts of soil, from light, sandy loams, through gravelly, to clays and adobe. Crop this year was abundant and often luxuriant. The growth was good early in the season and such early growth gave a vigor to withstand the colder weather later on, when vetches, at least, made little or no growth unless it be in rooting. The growth in March and April was great, for the season was ideal for vegetation. Little reference was made to the size or abundance of the nodules, which should have special attention as indicating the specific work of these nitrogen conserving plants as related to that special field.

Turning Under.

The time of turning under the crop will be partly determined by the time of sowing and the method will vary in keeping with the equipment of the ranch. Evidently cover crops will make a demand for disc harrows and plows, for while the ordinary plow can turn under even a heavy crop of vetches, the disc seems to do the neater and in every way more satisfactory work. Ranchers with small acreage may find here a chance for cooperative farming.

This plowing began in February with a fortunate few, but in most cases extended through March and April, while some fields are still unturned, offering, I fear, some perplexing problems in the summer's cultivation.

Where the crop is not too heavy it may be thoroughly disc harrowed, then plowed; the heavier crop demands the disc plow. After being plowed one way, the land should lie for some three weeks, when it can be cross-plowed and then soon can be shaped by the cultivator for irrigation.

Mission of Cover Crops.

This query brought various answers, some of them, perhaps, based more upon theories than being the outcome of personal observation. The question is important and it may require several years of comparative study to learn whether such cover crops supply nitrogen in sufficient quantities or in excess of need; whether roots and vine provide abundance of humus; whether the nitrogen thus gathered and made available from the atmosphere in the earth also liberates in the soil other fertilizing elements essential to successful culture or, in deed, whether barnyard manures or commercial fertilizers were best fitted to supplant the cover crop.

I quote some of the replies given. "First place." "Not any." "At the top of the list." "Equal to a coat of manure." "Merely a humus maker." "If planted both ways it largely supplies the nitrogen and the humus." "Indispensable in producing nitrogen and humus." "For young trees no additional fertilizer is needed, unless it might be for Valencias and lemons after the age of ten years chiefly valuable for formation of humus." "Expect some results from nitrogenous food but most results from humus added."

Mr. C. C. Teague writes: "First place, supplemented by commercial fertilizer. Should supplement but not take the place of fertilizers, except possibly, in a measure of nitrogen." Another said: "More to supply humus and prevent irrigation hard-pan than distinct food for trees."

In the open discussion emphasis was laid on the value of cover crops in eradicating hard-pan in the orchard. "Cover crops secure nitrogen and furnish humus which will help to set free the potash and phosphoric acid already in the soil in abundance. It will not alone supply the essential soil elements, but in time may take the place of some of the heavy fertilizing."

In spite of these differences of opinion, all purpose to continue planting, and nearly all seem content with the one inoculation or to the tubercles found naturally in the various clovers and legumes.

Some of the suggestions offered may be of value. Cover crops are a great saving of labor and for winter use at least are a great gain to the orchard. Burr clover grows in favor as having power to renew the land and as being self-seeding. Early planting, which should be drilled in to avoid loss of plants from drying out, will give the crop a start sufficient to maintain growth in the cold weather.

The capacity for producing nitrogen seems to be self-adjusting, for if nitrogenous fertilizers are used with the crop large growths result for plowing under, but the supply of nodules

on the roots will be decreased, while the finest nodules will be found in soil poor in nitrogen. Thus we see here an illustration of the remedial power in nature.

In Conclusion.

It would seem that our ranchers are determined to give cover crops a fair trial. Experiments in various kinds of plants should be carefully noted, with the different treatment accorded them and the fertilization used as a supplement. Would it not be wise to report their results until facts have become generally known and the use of cover crops has been put on a scientific basis and present guesses shall become knowledge? Special attention should be given to their province in gathering nitrogen and forming humus and to learning just what is their function in the matter of fertilization. The effect upon the soil of the previous year's crop must be noted and would it not be well for a few ranchers in every district to make varied experiments with cover crops as is being done by the management on some of the larger ranches?

THE CROP BENEATH THE SURFACE.

Without the crop below there can be no crop above the surface. And it is not surprising that there are weeds to destroy the crop below just as there are weeds to struggle for supremacy above.

Soil fertility—what is it, what makes it, and what destroys it? Fertility means the chemical elements necessary to plant growth, so proportioned as to make a complete plant food, and so arranged as to be available. Plants live as we live—on prepared food. We go to a hotel. It contains the food necessary and at the right time the cook prepares it, and if we have paid the price the supply is at our command. At other times the food is raw, and locked in the store house where we travelers can't get at it.

Plants grow by taking up certain amounts of carbon, oxygen, nitrogen, phosphorus, sulphur, iron, potash, etc. But these things are locked in the soil and it takes the assistance of the soil chef and steward to make the supply available and palatable—if we may use that term in this connection. The stewards and chefs of the soil are microscopic plants—bacteria—of different kinds that change the raw material of the soil into available plant food. They attack the chemical compounds and unlock the simple elements they contain so the plant roots can absorb them.

This crop of bacterial plants beneath the surface of the soil needs cultivating just as the crops above. They require air, warmth, moisture, food, and a certain condition of the soil or they will not multiply and aid the larger plants to get their food fast enough. Soils don't generally lack fertility. It is estimated that there is enough nitrogen in the average soil to last nearly a century, enough phosphoric acid to last about 500 years and enough potash to last twice as long. But the little stewards hold the keys and will not let the plants help themselves to these things. So it is a question of how to grow the crop beneath the surface that we may get a crop above.

We well know that if we get oats thick enough they smother out the weeds, or if we let weeds have right of way in the cornfield or potato patch we get no crop. We well know that if we let a crust form on the soil that air can not reach the roots and the plants do not thrive. This lack of air checks the growth of soil bacteria that are making plant food, so if they go on a strike for lack of air the crop depending on them must wait until they resume work. Cultivation is necessary to get air to the crop of microscopic plants below. We know, too, that if we let too much moisture leave the soil the crop withers. We have killed or checked the growth of our crop below so the food supply is cut short. Conservation of moisture is necessary, then, for other reasons than we usually give.

Ground may be too wet. It drowns the bacteria, or maintains such a low temperature that they do not thrive. These little plants need a temperature between 60 and 80 degrees. Drainage warms the soil earlier in the spring and puts these little friends to work preparing food for the coming crop.

Another thing: if the soil is too sour the right kind of bacteria fail to grow and weed bacteria take their place. Or it may be so acid that neither thrive and plant life is checked. On the other hand soils may become too alkaline for plant life. This is seen in the alkali regions of the west. Soil bacteria do best in a neutral or slightly alkaline soil and anything that throws it out of balance is poor farming.

Some bacteria are weeds: they are not desirable at all. For instance, there are denitrifying bacteria that attack the nitrates in the soil and break them up into nitrites and free ammonia or free nitrogen. It escapes and is lost. These bacteria grow best when oxygen is scarce. Thus a crusted soil favors the growth of these little enemies—weeds beneath the surface. Good culture thus prevents a loss of nitrogen.

Soil bacteria need feedling that they may get a start. Thus an application of manure aids them when conditions are a little adverse. But the application of manures must be wisely made that this valuable substance be not wasted or consumed by the weeds in our bacterial family.

The manure spreader, applying the manure daily, is the best method to feed plants and avoid loss of manure. It cannot then heat or leach away, or the nitrogen be consumed by the nitrifying bacteria it contains.—Successful Farming.

FARMERS' INSTITUTE.

J. B. Neff, conductor of the Southern California Farmers Institute, announces an institute at Ventura on June 24-25, and one at Fillmore, June 26-27. Pomona is also slated for one either following or preceding those two.

Prof. R. H. Loughridge of Berkeley will lecture on the chemistry of soils and Dr. S. S. Twombly will lecture on commercial fertilizers, and tell how to buy and use them. Other good features are promised.

THE DROUTH IN CUBA.

The Cuban shortage in rainfall seems to be as bad, if not worse, than our own, inasmuch as it is said to be worse than has been experienced in the last sixty years. It covers the entire island so that sugar and tobacco sections as well as those devoted to minor culture, and pasturage are suffering alike. No cane can be planted. Cattle are dying of hunger and thirst; wells are dry and the outlook for crops bad. There will be a great falling off of cane, tobacco, garden produe, oranges and pineapples.—Florida Agriculturist.

IMPROVEMENT OF CATTLE.

(Continued from First Page.)

case may be. There is some question as to the number of crosses that must be produced before this high standard of excellence will be secured in the grade. This will be somewhat dependent on the duration of the purity of the improving blood, the prepotency of the individual sires, and the plasticity of the common females. Instances are on record where ideal high grades have resulted from the third cross; in general, one would be safe in counting on at least the fifth. We must not, however, lose sight of the fact that while a high grade may eventually equal the improving breed from a standpoint of meat or milk-making, that it can never be possessed of a pedigree, nor equal the full bloods for a standpoint of prepotency in breeding; this is the principal argument used against grade sires.

In illustation on cover four yearling females are shown. The two in the upper row are pedigreed Shorthorns bred from college stocks; the one in the upper left hand corner, Sharon Princess, sired by Grenallen was not possible to trace the sires of individual calves. While these two grade heifers illustrate well the possibilities of up-grading, it is unfortunate that the number of generations since their improvement began can not be determined. We again remind our readers of the statement made in a preceeding paragraph relative to the possibilities through up-grading, and leave them to judge for themselves to what extent the illustration bears out our argument.

Breeding experiments are now in progress at this college to determine how many generations must be produced before animals can be secured equal to the improving breed, from a standpoint of utility, but some years must elapse before results can be secured.

We also suggest that at the time of the purchase of the pure-bred sire, one cow, or possibly two of the same breed be secured. The progeny of these two or three registered animals should grow into a nice little herd at the end of ten years, which could be used to replace the poorer of the high grades. That the high grade can be successfully produced as described

Illustration No. 2

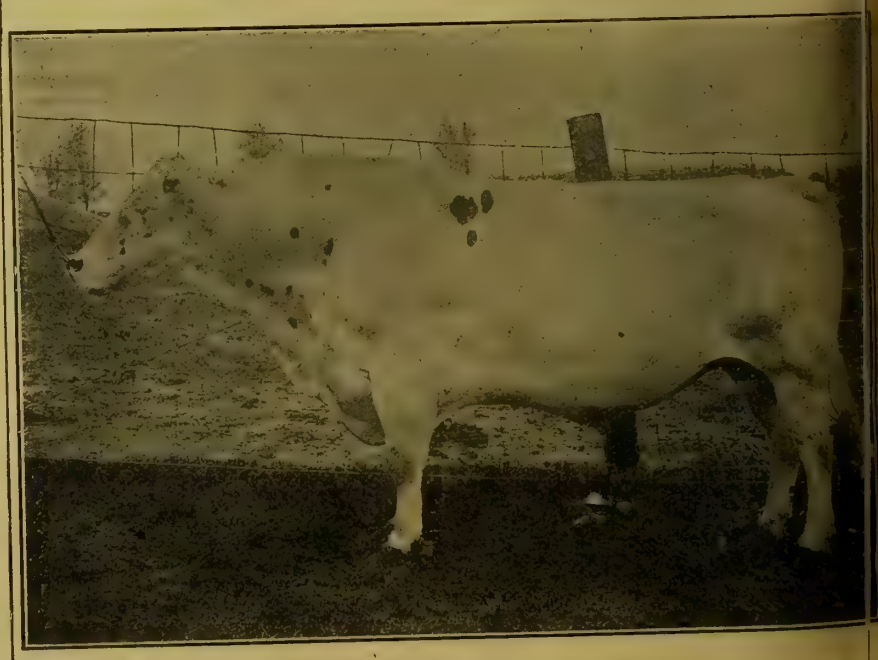

Illustration No. 3

38892, out of College Sharon, Vol. 49, page 949; the one in the upper right-hand corner is Mysie's Opal, sired by Gwenallen, and out of College Mysie 5th, Vol. 40, page 753. The two females in the lower row are simply high-grade Shorthorns which are out of Shorthorn grade cows purchased in Tuscola county, Michigan, by the Michigan Agricultural College in the fall of 1904; as the cows were in calf at the time of purchase and as the carload was picked up one by one, it can not be disputed, and its value have already been clearly demonstrated. The high grade forms the bul of the Western feeders coming to ou feed-lots; it makes up almost the su total of the 400,000 prime steers whic annually cross the Atlantic; it ha occupied no mean place in the list awards in fat classes at State, Na ional, and International live-stoc shows.

We desire at this point to emph

size the fact that the use of improved methods of breeding alone will not avail; it is absolutely necessary for these to be supplemented by liberal feeding and proper care and management.

Discarding the So-Called Aged Bull.

In general, it can scarcely be said of a bull, that he has reached full maturity until 4 years old, though this perfect stage of development is commonly regarded as being attained at a somewhat earlier age among some breeds. It has been a common practise for years, among farmers, to send the 3 or 4-year-old bulls to the block, largely because there is no sale for them as breeders. The general rule among prospective purchasers is to search for nothing but young bulls, yearlings or less, with the idea that they will grow into money for them, if they can dispose of them before maturity. It is false economy to purchase on this basis solely and take more or less chance on a young, untried animal when the actual results from a mature animal may be ascertained. There are two principal reasons why sires are usually sent to the block at 3 or 4 years of age. First, it is claimed that their dispositions do not mellow with age, and second, they become too large, heavy and clumsy, and it may lead to impotency. In answer to the first of these objections, we believe that except for the inheritance of mean, treacherous dispositions, bulls, in general, return on the points of their horns only that which is dealt out to them on the points of the fork, or in other words, the bull responds to the character of the treatment and management given him. Mature bulls should not have a tendency toward impotency if properly fed, managed, and exercised, but because of the fact that the bull is isolated, he is frequently neglected to a greater extent than any other animal on the farm. Too many bulls are fed irregularly and improperly, and confined constantly for long periods in small, dark, filthy box stalls; these conditions are not conducive to good breeding qualities.

There are some decided advantages in purchasing mature bulls. One of the greatest of these is found in the fact that the buyer can ascertain something relative to the character of their get; this is most important to the breeder of dairy stock. Another advantage arises from the fact that there is always more or less uncertainty regarding the future development of the bull calf, while this factor is entirely eliminated in the purchase of a mature sire. It is also not unreasonable to conclude that a mature sire will beget more vigorous offspring, especially because the young ones are frequently used to excess. Three and 4-year-old bulls can generally be secured at very reasonable prices. Some of the best show cattle we have seen were sired by bulls far past the mature stage. The expert breeder appreciates the value of mature sires. Attention is directed to the Shorthorn bull, Gwenallen, shown in another column, now 10 years old and in active service in the college herd; also Count Colantha Alban, 8 years old, illustration No. 3, at the head of the college Holstein herd.

Illustration No. 2 represents an Ayrshire cow calved September 20, 1900. By the time this cow was 37 months of age she had produced her second calf. In October, 1903, this cow weighed but 718 pounds, when in about the same condition of flesh as that shown in the illustration. Ten or fifteen years ago when dairy cattle were not bred to produce at such early ages as at present the average weight of mature Ayrshire cows was about 1000 pounds.

Cross-Breeding.

A cross-bred is the progeny of two distinct breeds. Though there has been an indiscriminate mixing up of the blood of various breeds, cross-breeding in its strictest sense is not prevelant, owing to the small number of pure-bred females in existence. The grades of the various breeds, however, are crossed frequently. The pratice has been stimulated by sudden and somewhat prolonged fluctuations in market values; a depressed dairy-market leads to more or less crossing of beef blood upon dairy types and vice versa; an increased price for the longer and coarser staples of wool always causes more or less crossing of coarse wools upon fine wools, or the reverse, as the case may be. No breeder can make such radical changes as these, frequently, for every time he alters his breeding operations so radically in trying to meet market fluctuations, he introduces factors leading to the final deterioration of his breeding stocks. It is much safer to choose some definite line of production, and stand by that through the temporary ups and downs of the market; the men who have done this have made a success of animal-breeding. It would not be sensible to say that no changes should be made in one's breeding operations; if a man is sure he has made a mistake, the only rational thing to do is to make a change, but these should not be made often, as they are usually attended by some loss. The progeny from some first-class crosses have shown highly desirable results, and while cross-breeding is more justifiable in the production of market animals. it can not be employed contin-

MILK CANS ROB YOU

Look through a microscope at milk set to cream in pans or cans and you'll see how they rob you. You'll see the caseine—the cheese part—forming a spidery web all through the milk. You'll see this web growing thicker and thicker until it forms solid curd. How can you expect all the cream to rise through that? It can't. This

caseine web catches a third to half the cream. You stand that loss just as long as you use pans or cans for they haven't enough skimming force to take out all the cream. But, just the minute you commence using a Sharples Dairy Tubular Cream Separator, you stop that loss.

Sharples Dairy Tubular Cream Separators have 10,000 times more skimming force than pans or cans, and twice as much as any other separator. They get all the cream—get it quick—get it free from dirt and in the best condition for making Gilt Edge Butter. Caseine don't bother the Tubular. The Tubular is positively certain to greatly increase your dairy profits, so write at once for catalog I-260 and our valuable free book, "Business Dairying."

The Ornamental Garden

By ERNEST BRAUNTON

THIS MONTH.

IF YOU haven't already done so, make a back-yard lawn. Too many farm homes have no patch of green to rest the eye, to give a cooler, more restful appearance, or, to be more prosaic, to sun the linens of the housewife.

It's not easy to make a fine, large lawn, but while waiting for that, spade up the back yard, thoroughly wet, level or smooth off, sow a pound of blue grass to each 200 square feet, mulch with a half-inch of the dry dust scrapings from the dairy yard, wet two or three times a day for a month or two and see what a beauty spot you have. It will beat the bare, hard-trodden back yard in appearance and the clippings give a fresh taste of green to the poultry now and then.

It's already late, so get busy.

Amongst other work this month chrysanthemums are planted in the open. All other summer flowering plants, like Verbena, Petunia, Balsam, Zinnia, take the place of the winter flowering bulbs which are stored away in a cool place for the next season. The planting of carpet beds of Coleus, Iresine and Acheranthus still goes on this month. Dahlia, Hollyhock, Amaryllis, Azapanthus, Canna bulbs will bloom all summer if planted this month. Special care should be taken to have the ground manured heavily with old manure, and that these plants get plenty of water, as they must be kept growing vigorously in order to have a profusion of flowers.

WATERING HOUSE PLANTS.

See that your flower pots have proper drainage, and when you water, do it most thoroughly. Air is as necessary to the roots of a plant as it is to the top, and when confined in a pot soon loses its life-giving properties, and must be changed. You may drive out the foul air by a thorough watering and then when the water dries out it will be replaced by fresh air, thus giving perfect ventilation to the soil.

Having this knowledge we should avoid light sprinkling, except for the benefit of the foliage, for as far as the soil conditions are effected, the benefit is almost nothing. What is worth doing at all is worth doing well; see that the drainage is free enough and the watering thorough enough so that this all-important work of aeration will be performed.

A RED, WHITE, AND BLUE DESIGN.

Where is your patriosm?

Why not symbolize it by having a red, white and blue flower bed as a certain Grand Army man has.

A walk leading to a pleasant seat in the garden is bordered on one side by an old-fashioned "ribbon bed," as they used to be called—that is a border in stripes each stripe a distinct, low-growing flower.

The thing to be careful of is that the plants grow to equal height and blossom at the same time. Plant a border of blue lobelia which you have previously started in the house. Let the next row be white alyesum which you plant in the open ground. The third row should be if possible be red phlox, but you must start it in the house in order to have it in bloom in time. If you cannot count on phlox of the distinct red color, of course red geraniums can be used, but you get no such mass of red as you do with the phlox. Red portulacca will do.

Don't hestitate to use the shears every day or two so as to keep the surface and the lines even.

At the end of the walk is a seat under an arch of blue and white morning-glories (there might also be red ones). Before the seat is a circular bed. (It would have been prettier if a star of red, white and blue).

It is six feet across. A mass of scarlet salvia three feet in diameter is in the center. Around this are white candytuft and white petunias covering the whole bed except the low-growing border of blue lobelia.

To make a star bed a circle of the desired diameter should have been drawn by driving a stake in the ground at the middle point of the bed, fastening a cord loosely to it with a marker fastened on it just far enough away to mark around this center a circle of the right size.

Having gotten the circle, a piece of twine long as its circumference should be divided into five parts. With this as a measure, mark off the circumference into five parts. At each mark will be a point of the star.

Lines drawn between alternate points will complete the star.—Kansas Farmer.

PANSY CULTURE.

The bright little pansy face which greets one from its flower bed is a flower loved by all. It is called "Heart's Ease" and is only the big sister of the humble little violet. It is wise to buy only the best seeds, for there is a vast difference between the fine and hybrid species. It is best to start pansies in the house, and this is how one woman starts her young plants, and they are always large and beautiful. She bakes the dirt in the oven, which kills all the weed-seeds and tiny bugs in the soil. Then this is sieved, mixed with sand, then shallow cigar boxes are filled with the mixture. Pansy seeds are sown, but in this case it is best to cover them slightly with the soft earth and moisten slightly by absorption from the bottom of the box or the seeds may all sprout in one place. As they grow and develop, select only the strongest for the flower beds. To make pansies flourish they should be sheltered from all but the morning sun, blossoms must be picked each day, for it is earnest in propagating its own species. They like moderately rich garden soil, and repay any kindness shown them in beautiful flowers.—Woman's Daily.

CLEMATIS.

California contains two very desirable species of clematis. We grow many vines not nearly so well adapted to our climate and as many that are less ornamental. The lowland or valley species (C. ligusticifolia) bears a profusion of small, white flowers and is neat and graceful in appearance. The foothill species (C. lasiantha) is a beauty and is superior to any of the small flowering species from other lands. It bears a profusion of cream-colored blossoms, so profuse in many cases that at some distance the tree over which it climbs looks as though draped with a mantle of cloth. Either species is easy to transplant in late fall or early spring.

ROCKWORK IN THE GARDEN.

Rockwork plays an important part in the landscape gardener's art. But great undertakings which require skilled artisans, an endless amount of stone and much expense are confined chiefly to public parks and gardens. Boulders artistically arranged about a fountain, with a leafy canopy overhead, are for the favored few; but a few stones judiciously placed are within the reach of the majority and will afford more pleasure in proportion to the time consumed in the making and in space occupied than could be obtained in any other way.—Garden Magazine.

Don't let the spring go by without planting something that will be permanent. Teach the children to each plant a tree, care for it and learn to love it. Show them the value of trees, not only commercially, but for comfort, beauty and health.—American Farmer.

If the cut worms are ruining the plants, slake about 5 pounds of good, fresh lime and add an ordinary sized wash tub full of water. Wet the ground about the plant with the lime water. It is said to fix the worms at once.

To prevent mildew spray bushes soon as leaves appear and several times during the summer with potassium sulphide (liver of sulphur) one ounce to four gallons of water.

Sanders-Arnott
Orchard Disc Plows

Forty-five of these plows have been sold by one agent at Riverside this season.

Used and endorsed by Arlington Heights Fruit Co., Riverside, Cal.; Chase Nursery Co., Riverside, Cal., and hundreds of other prominent orchardists throughout Southern California.

The Vegetable Garden

By ERNEST BRAUNTON

TREATING POTATOES FOR SCAB.

POTATO scab is a disease produced by a fungus. From the farmer's standpoint, however, the fungus is sufficiently well-known to enable him to guard against its ravages. The spores of the scab fungus are capable of living in a soil for a considerable time even without the presence of potatoes. They will also maintain their power of germination when packed away in manure. From this it naturally follows that soil which produced scabby potatoes last year should not be used for the potato patch this year. It is also plain that manure which is apt to contain spores of the scab fungus should not be applied to the potato patch this spring. A popular belief prevails that lime produces potato scab, and that barnyard manure does the same thing. This is an errouneous opinion because nothing can produce potato scab except spores of the scab fungus. This scab fungus, however, thrives best in an alkaline soil and a heavy coat of barnyard manure or a dressing of lime causes the soil to become alkaline, consequently, if there are spores of the scab fungus in a soil that has been treated with lime or a heavy dressing of barnyard manure, the conditions of that soil favor the growth of the scab fungus. This fact is the cause of the popular belief that lime and barnyard manure are direct causes of the potato scab.

A poorly drained soil favors the growth of the scab fungus, because such a soil is sure to have an alkaline reaction. In view of these facts it can readily be seen that it is not desirable except in localities where scab is not known, to manure land heavily for potatoes just prior to planting, nor is it desirable to give such land a dressing of lime. A well drained soil should be selected for the same reason as explained above. We speak of these things because unless the soil is reasonably free from scab fungus, treatment of seed potatoes with formalin, as recommended below, will do comparatively little good. It is just as important to rotate potato crops as it is to rotate other crops on the farm.

Treatment of seed potatoes for scab is as follows: For each 40 or 50 bushels of seed potatoes purchase at your local drug store one pound of formalin guaranteed to contain 40 per cent. of formaldehyde. Put this pound of commercial formalin in a barrel containing 40 gallons of water and thoroughly stir the mixture. Before cutting the potatoes put a convenient quantity, say from one-half to three-fourths of a bushel, into a gunny sack and immerse the sack containing the potatoes in the formalin solution mentioned. Leave the tubers in the solution for one and one-half hours, then remove, drain and spread them out on a clean floor or blanket to dry. As soon as they are dry they are ready to be cut and planted. Remember that formalin is not a poison and that there is no danger in handling the potatoes after they have been treated. Forty gallons of this solution is sufficient for treating from 45 to 50 bushels of potatoes. The solution, of course, may be used over and over, that is, after one lot has been soaked in the solution it may be removed and another added until the number of bushels mentioned have been treated in the quantity of liquid recommended.

Bear in mind that if you plant scabby potatoes on clean land you are sure to harvest scabby potatoes. If you plant potatoes, after having treated them with the formalin solution mentioned, on land that contains scab fungus spores, you will be little, if any, better off as a result of the treatment. In order to get a crop free from scab, you must plant potatoes free from this disease on clean land. If you will do this you need not fear harvesting scabby potatoes regardless of the character of the season. It does not matter whether the season is a wet or dry one, whether the land is rich or poor, unless spores of the scab fungus can get into the ground either through the seed or through soil infected with them, you cannot secure scabby potatoes. It pays well to treat seed potatoes for this disease.

ORIGINAL HOMES OF POPULAR PLANTS.

There are several classes of immigrants of which no records are kept by the department over which the United States Commissioner of Immigration presides; but they are immigrants that, in their own quiet way, have done much to make the new world more like the old. These are trees and plants; and if the new world has drawn somewhat heavily on the old in this particular, it has paid its debt in kind. The following are some of the immigrants:

Celery originated in Germany.
The chestnut came from Italy.
The onion originated in Egypt.
Tobacco is a native of Virginia.
The nettle is a native of Europe.
The citron is a native of Greece.
Oats originated in North Africa.
The poppy originated in the East.
The pear and apple are from Europe.
Spinach was first cultivated in Arabia.
The sunflower was brought from Peru.
The mulberry tree originated in Persia.
The gourd is probably an Eastern plant.
The walnut and peach came from Persia.
The horse-chestnut is a native of Thibet.
The cucumber come from the East Indies.
The quince came from Crete.
The radish is a native of China and Japan.
Peas are Egyptian origin.
Horse-radish is from Southern Europe.

PROTECT YOUNG TOMATOES.

When setting out your tomatoes some sort of shade should be provided for a short time until the tender plants can get firm roots in the new soil. Don't look for tin cans and boards all over the place.

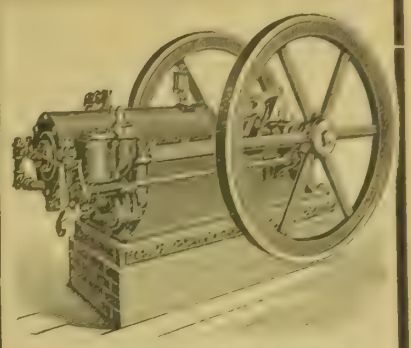
But take a few old newspapers and tear them in sheets about one foot by eighteen inches and put them over the tender plants and fasten them by means of clods laid on the four corners. This is much better than cans for it allows the air to get to the plants and does not bleach them, and when the plants are rooted, in two or three days the clods can be kicked off and the wind will quickly dispose of the papers, and there will be no cans to carry off again. A Subscriber, Covina.

GO FOR THE DIABROTICA.

Striped beetles, which appear early in the game and attack your cucumber and melon vines, are like Kipling's "Fuzzy Wuzy," that isn't afraid of "the British infrantee." As a repellant use a tablespoonful of bisulphide of carbon with a quart of air-slacked lime; sprinkled around the vines it is suggestive of a Chinese bomb to them. If, however, they do not take the hint, make a small tent, or, if vines are not large, invert a wash tub over the vine, and then put a tablespoonful of the bisulphide in a saucer and place it under the tub, closing it down tight by putting earth all around the rim. This will kill the aphis and other insects that trouble the plants. Remember, always, the bisulphide is inflammable, like gasoline.

Procure good seed of reliable seedsmen, no difference what varieties you decide upon. There is very great improvement made in vegetables as well as in other things, and the best is the cheapest is surely true in procuring seeds if in nothing else. Get the best, then give the best of care. With these two "fors" the garden will look well, no difference how many "againsts" there are, except annihilation, and if weather is favorable your garden will be a beauty spot as well as a money spot. Well grown vegetables are surely a nice sight.

There was a fair maiden Rose,
Whose actions were quite lachrymose;
When she saw a sad play
To sobs she'd give way,
And tears trickled down to her tose.



LAMBERT ENGINES

Are Superior to All Others

No Leak Cylinders
Cast in one piece with water jacket—no joint to leak—no gasket to blow out

Double Water Circulation
Prevents unequal expansion and contraction

No Gaskets to Blow Out
Ground joints only used

Insulation
Cannot wear, burn or blow out; it is permanent and indestructible

Economy of Fuel
We cannot claim that the "Lambert" will use 50 per cent. less fuel than some other engines, but we do guarantee that it will produce as much power for each gallon of distillate used for one year, or five years, as any engine on the market. This does not sound so big but means more

No Unreasonable Claims
The Lambert is not a "has been" or a "ging to be"; its record, past and present, speaks for itself.

LIVINGSTON & LEE
953 NO. MAIN ST., LOS ANGELES, CAL.

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

California Horticulturally

SEASONAL CONDITIONS.

FROM a Santa Clara valley correspondent comes the following notes of conditions now prevailing in that valley:

There are no two seasons alike in California and the present proves no exception to the rule. After the long continued rains extending well into March, we have had fair weather without ceasing.

Fruit growers have been put to it to get their orchards plowed or cultivated before the soil was too hard to work properly.

These conditions coupled with an apparent shortage of teams, has resulted in some instances in exhorbitant charges for team work. As much as $7 per day for man and team has been paid, when ordinarily $3.50 per day has been the charge.

Crops of fruit are generally light. Prunes in this section not more than 25% of last year's crop. Cherries generally light. Peaches perhaps 50%. Cots perhaps 1% of a good crop.

Sown grain crops look poorly generally, while volunteer grain looks better than usual.—H. G. Keesling, Edenvale.

BETTER THAN GRAFTING.

H. C. Keesling, of Edenvale sends to Cultivator readers the following valuable hint:

He is a poor fruit grower who does not add something to his knowledge, as the seasons go by. The longer one has been raising fruit the more willing he becomes to admit that he does not know it all, and is glad to learn something new.

How to cover the cuts on trees made in pruning, or the barked trunks caused by careless cultivation, was for many years a problem with us. Of course grafting wax made of one pound of linseed oil, two pounds of beeswax and eight pounds rosin can hardly be excelled for covering wounds, but it is too expensive for general use. Paint of all kinds we discarded years ago as ineffectual and expensive. Coal tar fresh from the gas works warmed and put on with a brush is second in our estimation to the mixture which we now use with great satisfaction.

It is simplicity itself: Melt rosin in one vessel and warm a little crude petroleum (the heavy fuel oil) in another. Pour into a third vessel three parts rosin and one part petroleum. Keep warm and apply with a brush. It seals the wounds effectually until grown over. It does not run in warm weather nor crack in cold weather. Cuts covered with this preparation three years ago are in good condition today. It costs only about one-quarter as much as paint.

APPLES AND IRRIGATION.

Mr. Shepard, of Hood River, in speaking of the irrigation of the apple, recommends as little irrigation as possible, and deems once or twice each year as sufficient, as apples grown with excessive irrigation, as in the Yakima valley, would decay more rapidly than non-irrigated fruit. He cautioned growers not to irrigate late in the season, as this would keep the sap flowing and cause serious injury to the tree by the bursting of the bark. Moderate irrigation enhances the color of the apple. Potash is a good fertilizer and its use produces a better color, larger crop, better seed and longer keepers.

FRUIT TREE LAW.

California has at last a law, to punish dishonest salesmen of fruit trees. Under the law as amended last winter, it is provided that, "it shall be unlawful for any person, persons, firm or corporation, acting either as principal or agent, to sell to any person, persons, firm or corporation, any fruit tree or fruit trees representing same to be of a certain kind, variety and description and thereafter to deliver to such purchaser in filling such order and in completing such sale a fruit tree or fruit trees of a different kind, variety or description than the kind, variety or description of such fruit tree or fruit trees so ordered and sold. And any person violating any of the provisions of this act shall be deemed guilty of a misdemeanor and upon conviction shall be fined in a sum not less than fifty ($50.00) dollars, nor more than five hundred ($500.00) dollars, or by imprisonment in the county jail not less than 20 days or more than six months, or by both fine and imprisonment.

Prosecution under this act may be commenced at any time within seven years from the time of the delivery of such fruit tree or fruit trees mentioned in section 1, of the law which is quoted above."

POWERS OF BOARDS OF HORTICULTURE.

The state law representing the duties and powers of the county boards of horticulture, as amended reads: Section 1. Whenever a petition is presented to the board of supervisors of any county, and signed by twenty-five or more persons, each of whom is a resident freeholder and possessor of an orchard, stating that certain or all orchards, or nurseries, or trees of any variety are infested with scale insects of any kind injurious to fruit, fruit trees and vines, codling moth, or other insects that are destructive to trees, and praying that a commission be appointed by them, whose duty it shall be to supervise the destruction of said scale insects as herein provided, the board of supervisors shall, within twenty days there after appoint a board of horticultural commissioners, consisting of three members, who shall be qualified for the duties of horticultural-commissioner, and shall hold office for a term of two years. Upon the petition of twenty-five resident freeholders and possessors of orchards the board of supervisors may remove any of said commissioners for cause, after a hearing of the petition.

Section 2. This act shall take effect and be in force from and after its passage.

The provision of the law which it is asserted the supervisors of several counties of the State are disobeying, is that which refers to the appointment of incompetent persons as Commissioners.

THIN YOUR FRUIT.

The writer recently passed a plum tree in his own orchard which was literally breaking with its load of fruit. It was soon relieved of a vast quantity, and yet retains, doubtless, altogether too much. Other trees were found in the same condition, and a man put to work at thinning. It is now getting late for this work, and every fruit grower should see that the trees are relieved of the extra burden of producing a lot of worthless pits, when with proper thinning, luscious fruit may result.

Nature makes liberal plans, and allows a wide margin for possibilities of loss. She usually aims to have enough, and something to spare. Hence if weather conditions are all favorable, our fruit trees are often over-burdened. They are in the unfortunate condition of the man who has taken that which he cannot complete, and do good work without a loss. The tree has not vitality enough to perfect in size and quality its full load of fruit.

It is quite evident that the disk plow is to be part of the equipment of the progressive farmer of the future. The double disk, or gang, is the style in most demand, for the reason that a double disk will cut from twenty-four to twenty-six inches with the same horse-power that it takes to operate the sixteen-inch mold-board sulky, and the cost is but a few dollars more. The disk plow is to be a very conspicuous factor in the future trade of the implement dealer, for it must be remembered the disk drill, the disk harrow and the disk cultivator, which have become popular with the farmers and give evidence of remaining so, were a long time proving that they had come to stay.

The greatest work has always gone hand in hand with the most fervent moral purpose.—Sidney Lanier.

With the Citrus Growers

WHITE FLY IN FLORIDA.

PROF. W. A MORRILL of the department of Agriculture who is investigating the white fly, so destructive to citrus interests of Florida, recently read before the Southern States' Association of Commissioners of Agriculture at Jacksonville a paper from which we quote sufficient to convince Californians that the last thing wanted in California is the white fly.

"The control of the white fly is a problem limited to the orange growing sections of the Gulf States. Its history as a pest covers a period of less than twenty years, but in its importance as a menace to citrus fruit-growing interests in Florida the white fly has already surpassed all other citrus enemies, both insect and fungus. Its spread into new territory is annually becoming more marked being hastened by the constant appearance of new centers of infestation. At the present rate, every grove in Florida will become infested during the next ten years with the possible exception of a few that may be favorably isolated. The work that is at present being conducted by the Bureau of Entomology of the United States Department of Agriculture was begun soon after the first of last July under the provisions of the Congressional Agricultural Appropriation bill for the present fiscal year. To those of you who have a general knowledge of the scope of entomological investigation it is unnecessary to explain that three months' work is insufficient in point of time for conclusive results in any but minor particulars.

What the Citrus Fly is.

The adult white fly is a minute insect about one-twentieth of an inch in length. The green-house white fly and the strawberry white fly of regions farther north, are its only near relatives which are of much economic importance in this country. The eggs are deposited on leaves of food plants and the larval stages appear much like certain soft bodied scale insects. At certain seasons of the year the adults appear on the wing in enormous numbers even to the point of resulting in considerable personal discomfort to the inhabitants of many of the towns of the state. It is but fair to state, however, that the chinaberry trees and not the citrus trees are mostly responsible for these large swarms of migrating adults.

Nature and Extent of Injury.

The citrus trees are seldom if ever killed outright by the attacks of these insects, but growth is retarded to a marked degree and sometimes entirely stopped. Injury is not only due to the extraction of the juices of the leaves by larvae and adults, but by the black fungous growth known as sooty mould which grows rapidly upon honey dew secreted by the insects. A simple chemical test shows that the soot covered leaves are unable to properly perform their functions of building up starch out of the food elements supplied by the roots. The fruit of infested trees is reduced in quantity, fails to ripen normally, and is of inferior quality and size. The size of the fruit is reduced from one to two sizes, according to usual estimates. On the basis of reduction of one size the decrease in yield amounts to twelve per cent. The decrease in actual number of fruit produced by infested trees would be conservatively estimated at twenty per cent. Moreover the fruit usually requires washing to remove soot before shipment, which is not only an expense but injures the keeping quality.

Prof. H. J. Webber of the United States Department of Agriculture estimated in 1895 that the loss occasioned by this insect was in the neighborhood of fifty thousand dollars per year. Since that time the pest has become more widely spread and destructive. Professor H. A. Cossard, formerly entomologist at the State Experiment Station, in his valuable bulletin on the white fly, stated it to be his belief that the decrease in yield caused by the insect was between twenty-five and forty per cent. and in 1903 the same writer placed the loss at a quarter of a million dollars per year. At present it is safe to estimate that the white fly has become established in one-eighth of the groves of the state, and if the entire loss in size, quantity and shipping quality of the fruit were but thirty-three per cent. in these infested groves it would equal fully three hundred thousand dollars per year, at the present rate of production.

Method of Control.

The success of all methods of control against the white fly is to a great extent dependent upon concerted action among all the citrus fruit growers in a particular locality. At the present time spraying is the only control measure which is practiced against the white fly. In some sections of the state, this has come into disfavor for various reasons. Among the greatest causes of inefficiency are poor methods of application and lack of thoroughness on the part of men engaged in the work. There is an opportunity for a large amount of work to be done in the line of determining comparative effeetiveness and cost of different materials used in spraying, as well as the maximum dilution possible in each case without diminishing the efficiency. Several instances have come to my attention where spraying has given entire satisfaction under circumstances wherein the results were not interfered with by the presence of adjoining groves left untreated, or by the presence of chinaberry trees. The trees mentioned are favorite breeding places for the white fly, and each tree is capable of producing many millions of adults, which by their habits of migrating in midsummer may nullify to a great extent the most careful spraying of neighboring groves. The importance of these factors should not be overlooked in estimating the benefits derived from the use of sprays.

Expense.

The expense involved in spraying is an important consideration, but the total cost of spraying a grove when regarded as a lump sum frequently seems more excessive than when the cost per tree is calculated. Until the advisability of some other method of treatment has been conclusively proven, spraying must be relied upon in most sections of the state to prevent the devitalization of the citrus trees by the white fly.

Fumigation with Hydrocyanic Acid Gas after the methods in common use in citrus groves in California was tried in this state a few years ago by the Experiment Station entomologist. The results showed the desirability of this practice being tested by the orange growers of Florida on a larger scale than was possible in these preliminary experiments. That this has not been done seems due principaly to the lack of demonstration of the methods involved. Plans are being made to continue experiments along this line during the dormant season of the citrus trees. It is hoped that in its value as experimental work and as a demonstration of the fumigation methods this will have a two-fold result.

Natural Enemies.

Three fungus diseases which destroy the lavae of the white fly are proving very beneficial in certain sections of the state. In Manatee county, where the two best known of these fungi have been longest established side by side, the experiences of the citrus fruit grower show that in a series of six years the relief by these diseases has amounted to about one-third of a complete remedy. This year these parasitic fungi have resulted in producing two-thirds of a condition of complete relief. This is owing, with little doubt, to atmospheric conditions being usually favorable to the growth of such forms of plant life.

It remains to be proven whether by artificial means these fungi can be disseminated and relied upon to give a satisfactory condition of relief from view of this season's experiences showing the degree of effectiveness these fungi may sometimes attain in inland localities, notably at Orlando, it is most strongly advised that each of the three parasitic fungi be established in every white fly infested grove in the state.

Thus far predatory insects, although not uncommon, have proven of but little benefit in reducing the number of the white fly. True parasites are at present unknown for these species, although of the seventy odd species of white fly known to occur in this county but twelve are subject to the attack of minute wasp-like parasites. These parasites in some cases are very effective in controlling the host species. In one case it has been calculated that over sixty per cent. of a certain species of white fly had been destroyed by this means. The success attained in recent years in allowing insects to fight insects leads to the hope that eventually some parasite will be found which will aid naturally in the control of the citrus white fly. As far as means for such work permit, efforts are being made to import into the state and to establish such parasitic insects and fungi as are known to attack species of the white fly, in other sections of this country and in foreign countries.

On the one hand the exposed condition of the pest under consideration rendering it specialy valuable to the attack of natural enemies and on the other hand the inevitable labor and expense of successful artificial methods gives basis to the prediction that complete control by natural enemies will be the eventual conclusion of the white fly problem.

A PLOWING HINT.

Did you know that trash ploughed under while wet will rot much quicker than if ploughed under while dry, no matter how much rain falls on it after being ploughed in? If you don't know it, then just watch it in the future. I have noticed it several times.

One year I began ploughing early in the fall, and the ground was very dry. I ploughed several days and decided to stop until it rained, when it would be easier on the team. It was two months before I began plowing again. When I began the second time the ground was wet, and all the trash was then well soaked. I ploughed it all under just as I did before, breaking the same depth, etc. When I examined the land early next spring I found that the trash I had turned under while dry, the first strip ploughed, was almost like it was when I ploughed it under, having rotted very little. While that ploughed under later but while wet, was entirely rotted.—Ex.

Your worth consists in what you are, and not in what you have. What you are will show in what you do.

Gold Medal Citrus Trees

Are fully described in our treatise of Citrus Culture, which is a trifle the best thing of its kind ever published. Contains about 50,000 words and 100 illustrations telling about oranges and lemons from the seed bed to the bearing orchard. Price 25 cents. Remember we are the largest producers of Citrus Trees in the world and stand ready to serve you with the finest nursery stock that can be grown. Correspondence invited.

San Dimas Citrus Nurseries
San Dimas, Cal.
R. M. Teague, Prop.

ESTABLISHED 1889
Geo. B. Warner
Orange County Nurseries
Grower and Dealer in Citrus and Deciduous Trees of All the Standard Varieties
Grafted Walnut Trees a Specialty
Budded Loquats, Roses, Grape Vines, Berry Plants, Cypress, Etc. Street and Ornamental Trees, Shrubbery, Blue Gums. Only clean, healthy stock offered
Residence, 202 E. Tenth St. Telephone S. S. Red 92. Santa Ana, Cal.

..OMBURT..
Nursery
1 Mile North of San Dimas
Only about 2000 Valencias left, 1-year buds, 3-year roots, fine trees $1.00 each to close them out
A few Nectar Pomelos left at same price. The finest pomelo in California.
O. M. BURT, at Nursery.
A. P. GRIFFITH, Azusa, Cal.

Orange Seed Bed Stock
We still have several thousand good one-year plants to spare. Better get your order in at once.
Southland Nurseries
F. H. Disbrow, Prop., R. D. 1, PASADENA, CAL.

VALENCIA ORANGE TREES
We have a quantity of first-class trees which have not been culled over, at reasonable prices. Also Washington Navel, Loquat Trees, Arbor Vitaes, Spruce, Cypress, Eucalyptus, Acacia, Pepper, Pine, Umbrella Trees, Roses, Palms, Etc.
Write for prices. Address
The Covina Nurseries, 1047 E. 46th St., Los Angeles, Cal.

Budded Orange Trees
One and two years old
For Sale
Heslop & Greenwood
Lamanda, Cal.

When writing advertisers mention Cultivator

Plant Your Trees This Spring
With plenty of water, this is the time of the year to plant
ORANGE TREES
The growth of a Valencia tree is worth $2.00 a year for the first five years. We have now ready for sale
7000 VALENCIA TREES
Azusa Valley Nursery
Address:

THE COYOTE NUISANCE.

Frequently letters of inquiry come to the Cultivator in reference to the coyote plague, especially in sparsely settled communities where depredations are large. These pests which destroy chickens, young pigs, lambs and even attack calves sometimes, do a great deal of damage in California annually.

How to dispose of these enemies of the ranch which continuously annoy the farmer and deplete his young stock, is treated in a recent bulletin on "Wolves in Our Forests," by the Forest Service Bureau of Washington. Of course, we do not have the big timber wolf in California, at least the gray wolf, of the middle-west country, but the coyote is near enough related to be much like it, and is also most damaging in its nocturnal assaults on the class of stock above referred to.

We quote the bulletin:

"In the use of poison it is of first importance to determine the amount that will kill with certainty in the shortest possible time. According to German and French authorities on toxicology, the smallest dose of strychnine that will kill a 25-pound dog is approximately one-half of a grain. Quadruple this for a 100-pound wolf and we have two grains. Mr. B. R. Ross, of the Hudson Bay Company, found that this quantity would kill a wolf quickly. Experiments by Prof. David E. Lantz, of the Biological Survey, would indicate the best results from a still larger dose. One grain killed a 21-pound dog in seventy-five minutes, while two grains killed a 40-pound dog in twenty-seven minutes, without acting as an emetic. For a wolf, therefore, four grains of pure sulphate of strychnine would seem to be a proper dose.

For wolves, place four grains of pulverized sulphate of strychnine in a 3-grain gelatin capsule, cap securely, and wipe off every trace of the bitter drug. The capsules should be inserted in a piece of beef suet the size of a walnut, and the cavity securely closed to keep out moisture. The juice of fresh meat will dissolve the gelatin capsule, hence only fat should be used. The necessary number of these poisoned baits may be prepared and carried in a tin can or pail, but they should not be touched with naked hands. Old gloves or forceps should be used to handle them. The baits may be dropped from horseback along a scented drag line made by dragging an old bone or piece of hide, or may be placed on, around, or partly under any carcass on which the wolves are feeding, or along trails followed by wolves. Partial concealment of the bait usually lessens the wolf's suspicion, while some kind of scent bag near by or along the trail insures its attention.

The gelatin capsule will dissolve in about a minute in the juices of the mouth or stomach. When the strychnine is taken on an empty stomach it will sometimes kill in a very few minutes, but when taken on a full stomach the wolf may have time to travel some distance before dying. In experiments on dogs the animal usually becomes helpless in one or two minutes after the first symptoms of poison, and dies five or six minutes later."

CAR SHORTAGE.

Shippers throughout the country are to be congratulated that there is now harmonious action between the common interests of consumers and railway operators. These several classes which have, in the past, worked at variance, are now operating in unison and the promise is auspacious that in the future the car shortage situation will be remedied.

"The American Railway Association, which held its sessions in Chicago, recently, adopted a rule providing that any railroad that does not promptly return a freight car belonging to another line must pay a five-dollar penalty. This fine is to be in addition to a daily charge or fifty cents, which every company will pay for each car on its lines after July 1."

In addition to this arrangement, the car clearing house system recently established in Chicago has arranged a publicity program to assist in the tracing of these vagabond freight cars.

The railway companies are realizing that they, as well as the shippers, are losing money through inefficient traffic management. This combination of self-interest will also benefit the people. Coming in the same week with the Mississippi decision that railways must pay demurrage charges to consumers and shippers for unreasonable delays in the movement of freight, the railway action of Chicago indicates that the persistent preaching of newspapers and the memorials of shippers have been having a beneficial effect.

The president preaching of the newspapers of the country against the dilatory tactics of the common carriers, have had the effect of calling the attention of the courts to the delays and consequent loss to both shippers and consumers by the embargo of the railroads against the producers.

California has sustained a serious loss by reason of the railroad situation, but there is every prospect that the future will be relieved of this condition and that our products will be sent to market without the delay which has heretofore attended the varied industries of California.

FARM MISSIONARIES.

In the state of Washington the University is considering a plan of employing traveling lecturers to go from farm to farm to consult with and advise the owners regarding the best methods of producing and marketing crops.

This idea is endorsed by many prominent experiment station directors who believe the plan of carrying information to the people who are busily engaged in pursuing their occupation is a good one and means much for the advancement of the calling in which they are engaged.

In California, we have the horticultural commissioner system which takes the place of traveling lecturers proposed for Washington, and when these commissioners are experts, like J. W. Jeffrey and S. A. Pease, they can be of inestimable service to the horticulturalists of the district in which they operate.

In general we like the idea of sending missionary lecturers to the agricultural districts. The Spokesman Review well expresses the thought when it says:

"The missionary idea of carrying the gospel to every creature is not confined in its usefulness to religious work. In all departments of life it is seen that the beginnings of instruction must be forced upon the people to a certain extent. That is to say, their interest must be aroused from a source not of themselves. Invitations to attend meetings and hear valuable lectures are neglected largely by those whom it would most benefit.

"Instances are not lacking of this idea of farm missionary work. "Corn trains" have been fitted up in the central west and hauled by the railroads from town to town educating the farmers how best to breed and raise corn. There is a record of a "poultry train" doing the same kind of work. A movement is already on foot to put on a "wheat train" to teach the farmers of the Inland Empire how to make the most profits in raising grain. These trains are accompanied by instructors who go from place to place, carrying information and giving instructions to those who otherwise will go on "in the same old way," while their more progressive neighbors are extracting money from farming. Creamery men also have found much to do in this sort of missionary work. Tneir wide-awake agents are constantly preaching what are the best kind of cows to keep, the best method of feeding and how to profitably care for and ship milk. So it is all along the line."

The new agriculture demands much in the line of missionary work.

SCHOOL GARDENS.

One of the pleasant signs of progression in our public school system is the establishment of the school garden. In several eastern cities the experiment is being tried and the consensus of opinion on the part of trustees and teachers is that pupils are interested, educated and elevated by the influences of the flower garden. It is found that the little children seven to nine years of age acquire more general knowledge of value in doing things than they could get from sloyd work, manual training, or book study alone. We expect in a few years to see an hour's garden work each day given to every child in the primary grades in all schools.

As a general proposition, the garden is not alone for the beautiful flowers and fresh vegetables conveniently at hand for every summer day, but for the pleasure of producing this supply out of one's own soil and watching its daily growth and development. The vegetable garden hardly less than the flower garden, and flowering shrubs typifies the ever advancing seasons whose changes make up the never failing charm and pleasure of out door life.

NO REACTION.

Fears are expressed by some well advised citizens that the advanced ground taken by President Roosevelt and his supporters will be lost if he is not returned to the presidency in 1907.

There is no ground for any such fear. Every adminstration has been progressive; has been ahead of every other administration.

American history does not describe or make known any reactionary period. No good American statute once enacted has ever been repealed. None ever will be. There is not a particle of danger that anything done by the last congress will ever be modified. Certainly no danger that it will ever be repealed. The president who succeeds Mr Roosevelt must be progressive. He must go ahead along just lines, always acting in fairness, but preserving the rights of all American citizens.

At this season (we mean now) it is the part of wisdom to spray for the codling moth and thus prevent wormy apples. Paris green is the best remedy and should be applied at least twice during the season. The first time soon after the blossoms drop and before the fruit turns downward. One pound of Paris green to 180 gallons of cold water. Make the poison into a paste before mixing with the water and while spraying should be kept constantly stirred. It should be applied again about sixteen days after the first application, and in some districts a third application is beneficial or less with soft varieties.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Grain is already being warehoused in Coachella.

Anaheim is also in line with the good roads movement.

Hogs are being fattened in the grain fields of Imperial Valley.

The harvest season is in full swing in the Coachella and Imperial Valleys.

A movement is on foot to build a boulevard connecting Yucaipe Valley with Redlands.

Over forty million gallons of water are flowing daily over the top of the great Hemet dam.

Perris is moving for better roads; especially one main throughfore leading into Riverside.

The City of Santa Ana contemplates buying a farm of 133 acres for the disposal of the city's sewage.

The Riverside Commissioners have made an appropriation for fighting forest fires in the reservations.

The Imperial Development Co. is constructing an immense flume to carry irrigation water cross the New river gorge.

Water Company No. 1 of the Imperial District is experimenting with a twenty-five horse power engine in cleaning ditches.

It is estimated the Imperial valley returns for products to be distributed in the immediate future will aggregate $3,000,000.00.

New threshing machines are being brought into the Santa Ana section for working in the exceptionally large grain crop this year.

Some of the outside districts of Los Angeles County are moving for three million dollar bond issue in the interest of good roads.

Orange county celery growers claim that the Southern Pacific owes them thousands of dollars because of the failure to move the crop.

Redlands is taking steps to effect the settlement of the Yucaipe valley where 14,000 acres of fertile land will be opened for settlement.

The City Council of Santa Monica has passed an anti-weed law, compelling the removal of weeds from lots as well as along street lines.

Los Angeles milk inspectors have given many dairies of Southern California a thorough inspection and demanded thorough clean-ups.

Summer squash is being shipped from Brawley. It is estimated that at least a car load will be the output from that one point this season.

The Salton is reported to be holding its own and not showing much fall from evaporation as yet. There is yet some flow of the river into the lake.

Holtville, Imperial valley, claims to be first in the market with a new crop of barley which was delivered to the Imperial Grain and Milling Co. there last week.

A large reservation consisting of about 2000 acres of farming land in San Luis Rey country is soon to be alloted among the Indians of the Pala Reservation.

The Imperial Creamery is now turning out a large quantity of butter; one day last week seeing 2200 pounds churned. The output for this month will exceed 20 tons.

Los Angeles and San Bernardino counties are moving for better forest protection in the forest reserves. Last year both counties suffered severely from destructive fires.

Dealing in agricultural lands about the Imperial valley is much more rapid since the feeling of security has come in the control of the waste water of the Colorado river.

A Santa Ana grower claims to kill army worms by feeding them ordinary bran with no poison, claiming that its power of swelling up, "all samee" dried apples, fixes the worm.

The ranchers of Santa Ana are contending with the owners of the Irvine Water Company regarding water rights which the big water company is endeavoring to deprive the ranchers of.

HORTICULTURE.

Thermal is taking steps to have a "Melon Day."

There will be good crop of pears at Hemet this season.

Highlands has shipped 1300 cars of citrus fruits up to this time.

Riverside has shipped nearly 4000 cars of oranges up to this time.

Black sage is in full bloom and bees are busily storing a good yield.

Riverside reports the army worm climbing trees and eating oranges.

Brawley fruit growers are constructing a large storage and shipping warehouse.

Over 5000 trees were fumigated in Riverside County for red scale last month.

Walnut trees are looking fine in the Hemet Tract and they have set a good crop this year.

The first crate of cucumbers out of Imperial district was shipped May 4, from Brawley.

Rialto Improvement Circle is moving for better roads and otherwise inspiring tidier places.

Coachella Valley is moving for one large shipping association to handle its output of fruits.

San Bernardino County has two power sprayers working against the powdery mildew on apple trees.

The Submarine claims that more than a thousand acres of the Coachella valley are planted to melons and grapes.

The Whittier News reports interest in the walnut industry as increasing more this year than at any time in the past.

Strawberries have been a glut on the market for the last few days, the Southern California crop being the largest ever.

Riverside Horticulture Commissioners report a month's active work for April, special attention having given to red scale eradication.

Rialto Orange Co. has contracted with the Rialto Citrus Union for packing the remainder of its crop which will be about 125 cars.

Bee Inspector Pleasants, of Santa Ana, reports the present as good working weather with the probability of a big crop of honey this season.

Cantaloupe growers in Coachella and Imperial Valleys are busy these days; vines full of bloom with a few melons already a third to a half grown.

Prof. A. E. Fry, one of the most prominent educators of the country is experimenting with the growth of pine-apples in Highlands.

The Southern California Fruit Exchange is making a strong move to secure more cars for moving the remainder of its citrus crop.

Two packing houses belonging to the California Citrus Union and the Rialto Orange Co. were burned last week with a loss of $25,000.

Whittier is having serious difficulty with the appearance of large numbers of army worms; in some instances even the larger fruit trees are attacked.

The advantage of the Rialto section as an orange producing community is becoming more recognized. Several large sales having been made by Riverside capitalists during the last two weeks.

E. E. Allen, of San Diego, is experimenting at Santa Ana in a remedy for walnut blight, wishing to pull down the $20,000 prize offered by the Walnut Growers' Association of Southern California.

The poultry business is developing into quite an industry at Hemet. There are several good sized chicken ranches located on the Hemet Tract. About fifty cases of eggs are shipped from this point weekly.

La Habra Walnut Growers' Association filed articles of incorporation with the county clerk last week. Capital stock $25,000. To grow, buy, sell, deal in, bleach, and treat walnuts is the mission of the Association.

Northern California

AGRICULTURE.

Tehama is making a move for better roads.

About 125 cases of eggs are shipped from Corning weekly.

Dinuba reports 15.91 inches rainfall as against 14.80 last year.

Anderson ships broom-handles to San Francisco by the carload.

S. H. Rambo has been appointed fire warden for Santa Cruz county.

Watsonville reports promise of fine prices for apples for the coming season.

San Jose Grange is advocating a "Peace Day" movement in the public schools.

Ukiah will soon have a new creamery; over two hundred cows having been pledged.

Lakeside country, in the San Joaquin Valley, reports extensive plantings of alfalfa.

State Forester Lull is giving special attention to safeguarding against summer forest fires.

San Francisco buyers are after the "spud" crop of Pajaro Valley; attractive prices are being made.

Wheat growers, of the great central valley, look with complacency on the soaring price of wheat.

The creamery on the Burdell ranch, two miles from Point Reyes, was destroyed by fire last week.

Kern, Fresno, Tulare and Tuolumne counties are taking steps to protect the forest reservations from fire.

The break in the levee at the Hoch farm, near Yuba City, has been closed by the pile-drivers within the last few weeks.

Nevada City complains that its road club is losing interest and enthusiasm in the good roads movement which was started some months ago.

Good progress is being made in the erection of buildings at the State Agricultural Farm, at Davisville; twenty men are employed at this time.

Sonoma County Driving Club is planning for races on June 1st. Automobile races will be admitted at the meeting of the Sonoma Driving Club at Santa Rosa.

Upper Lake Cheese and Dairy Company, of Lakeport, recently elected the following directors: Sam Jones, Jas. Mason, W. O. Ruddick, Geo. Ritney and W. E. York.

Corning reports the receipt of 60 tons of wool at its railroad depot in one week. This wool was raised around Henleyville, Paskenta, and other foot-hill towns.

The cattle quarantine has been removed from the southern and eastern parts of Fresno county, and cattle in these sections may now be shipped to any section of the State.

Sacramento is planning for a cordial reception to the National Irrigation Congress to be held there later; steps have been taken for the raising of $50,000 for the entertainment of the delegates.

A river meeting is called for Sacramento on the 21st of this month to discuss methods of improving levees, and otherwise controlling the damage from winter floods. Governor Gillett and Senators Perkins and Flint will be speakers.

The sheep men of the state held a meeting in Sacramento last week, and requested of the Governor the appointment of a commission to enforce the sheep inspection law pased by the last legislature. The committee agrees to furnish the funds necessary for the enforcement of the law.

Regarding the field crops about Yuba city, a correspondent says: There will be a heavy hay crop in Sutter county this season. Much of the acreage that was sown to grain and that was overflowed will be cut for hay. The excessive rains and water of the winter has turned much of the wheat into what is called "cheat," which makes fine hay, but which is of no use for seed purposes. On the ridges the growth of hay is particularly heavy.

HORTICULTURE.

Corning is reporting shipments of strawberries.

Grapes in Kings County will average about three-fourths of a crop.

Yuba City reports an immense grape crop; in fact, the heaviest on record.

Hanford reports an average crop of peaches in the country surrounding and prunes and apricots exceedingly light.

The strike situation in San Francisco is interfering with the best market results on small fruits.

A large amount of planting in Kings Country is reported: over a hundred thousand fruit trees with over half a million grape-cuttings are among the items reported.

The prune, peach, apricot, and cherry crops are bearing exceedingly light in the Santa Clara Valley. Col. Hersey estimating one-fourth or two-fifths of last year's crop.

The first shipment of cherries of this season was gathered in Vacaville and forwarded from Sacramento May 6th. The first of last year's crop was forwarded May 2.

A correspondent from Yuba City says that vineyards are in excellent condition and that the winters rains have been of vast benefit with fruit and farming interests.

Prof. Hunt, of the State Agricultural Department, is experimenting with the Bordeaux mixture for the treatment of pear blight and shot-hole fungus in the Hanford fruit district.

Northern California lumber men are experimenting, with assistance from the National Department of Agriculture, in the planting of eucalypts on cut-over lands in the redwood belt.

The stockholders of the Santa Clara Valley Fruit Growers Exchange have elected the following directors: Philo Hersey, C. F. Wyman, C. P. Bailey, H. A. DeLacey, D. Johnson, W. M. Herrold, J. T. Grant, F. H. Babb, and E. L. LeQuesne.

W. C. Walker, Pacific coast manager of the California Fruit Exchange, was in town yesterday. Mr. Walker has heretofore served the company in the Chicago district, but upon the resignation of Mr. Sprague as manager, he was chosen to succeed him.—Vacaville Reporter.

The supervisors yesterday granted the California Fruit Canner's Association the right to construct a spur track at Kingsburg to six acres of land recently purchased by the association. Application for right to build the track was made by J. M. Heron as manager of the Fresno branch of the canners' association.—Fresno Republican.

The Happy Valley strawberry, the Olinda strawberry, the best strawberry grown in the state of California, the strawberry that has made Shasta a prominent county for the luscious fruit, is now coming into market in quantity. Many crates are loaded into the express car on the Portland Overland train every morning for the Oregon market.—Sacramento Union.

The writer recently had the pleasure of a visit to the yards of Mr. W. A. Seymour, breeder of White Wyandottes. In his yards were same excellent birds, being the true Wyandotte type.

Mr. Seymour recently bought the entrie flock of White Wyandottes, of the Unique Poultry Farm; those birds with his own gives him not only a good flock, but a large one, but his yards are conveniently arranged and every order for eggs or stock will have Mr. Seymour's personal attention.

W. W. Howard, of San Jacinto, formerly of Los Angeles, well-known on the Pacific Coast as the originator and breeder of the Howard Strain of White Leghorns, is breeding this strain on a larger scale than before. Mr. Howard has a large trade on this breed, not only on the Pacific Coast but in all parts of the United States, and recently shipped a fine trio to Japan.

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Chicks Just Hatched We ship them everywhere. Pure Bred White Leghorn Chicks from the Best Egg Producers in the United States

California Incubator Co., Maxwell, May 27, 1906.
Gentlemen—The little chicks arrived in perfect condition. It is very remarkable that 600 little fellows would come so far and being so long on the way without the loss of a single one, but it is an undisputed fact that such was the case. We are thinking of getting a few more providing we can get them right away. Answer by return mail. Yours truly, J. F. Campbell.

Profit in the Poultry Yard

By FRANK H. THOMAS, Los Angeles, California

MR. THOMAS IN CHARGE.

READERS of the Cultivator have had the pleasure of an occasional article by Mr. Frank H. Thomas. It is with much pleasure that we now announce that he is to be a regular contributor and will have charge of this department in the Cultivator. He will furnish the leading article each week and be prepared to answer all questions on poultry culture.

His connection with the paper is such that he has a desk in the editorial rooms and is prepared to give immediate attention to any poultry matters submitted to him.

Mr. Thomas has had many years experience in poultry matters, beginning his work with thoroughbreds in Jacksonville, Illinois. From there he took many prize-winning birds to shows from Kansas City to Madison Square. Incidentally, at Jacksonville, Mr. Thomas engaged in the printing business, for which he had a large and successful plant.

Since coming to California, he has been identified with the poultry industry and has done some of the most intelligent and impartial judging and awarding of premiums ever given to California breeders, in the last two Los Angeles shows.

Thus he knows good birds, he knows how to raise prize-winners and producers of wealth from a commercial standpoint. For these reasons he is fitted to make this department of greater value to our readers than ever before. It's up to the readers to improve the opportunity and draw liberally on Mr. Thomas' abilities. If he doesn't give in the department what the subscribers want, ask for it.—Editor Cultivator.

THE RED MITE.

AT this season, we have to keep a close lookout for the most deadly foe to our flocks, the little mite.

The mite is the smallest of our pests, yet what they lack in size, they make up in numbers, and the rapidity with which they multiply will astonish any one. We have been told that a mite hatched today will be a great grandmother tomorrow. That we cannot say positively, for we have never become well enough acquainted with them to distinguish one from another. Without doubt, the numbers in an infested poultry house will run into millions. A single mite can do no narm, but thousands can. They seem to appear all at once; we have seen setting hens driven from the nest by them. We remember having bought a setting of fine eggs and putting them under a hen. After carefully dusting her, we put her in a clean nest with clean straw, and watched her every day during the period of incubation. When the eggs hatched, we left them in the nest over night, expecting to take them off the following morning, but when we went to get the chicks we found them dead and the hen gone. We succeeded in finding the hen; her comb was as pale as if she had been sick for a month and she could hardly walk from weakness. The mites had sucked nearly all of her blood.

The mites, when they first hatch and before they feast on a fowl, are grayish in color, but after they fill up on blood, this shows through the transparent skin; then we have what is called "the little red mite." In their natural color, you can hardly notice them on the roosts nor in the nest boxes.

We have had hens leave the nest, but on examining them could find no trace of either mite or disease. The mites that had been sucking their blood had all left and gone into the straw and would appear again the next night for another feast.

Besides the damage done by breaking up your hens from setting, some who claim to know, say that they will spread disease by feasting on a sick fowl and then on a well one, and in this way the whole flock becomes contaminated.

Since all are apt to be bothered with this pest, it is well to be prepared for them and know the best means to rid our houses of them. Since they have no lungs, as the large body-lice, or feather-lice, it is useless to use either a liquid lice-killer, or a dust on them, as the liquid will only kill what it comes in contact with, and the dust will only drive them off for a short time.

The best remedy we ever found is paint; as long as you keep your house painted, there are no cracks in which these pests can lay their eggs, and as they are very short-lived, you can soon get rid of them in this way. Another good way is to white-wash, but it is not the best plan to put too much white-wash on the roosts. Another good way is to spray about once a week with a kerosene emulsion; if this is done, you will have no trouble.

LITTLE CHICKS.

The chicks should not be hurried from the incubator to the brooder. They do not need food. They do need rest. The incubator is better for a day longer than is the brooder.

The brooder must be light on roof and sides, dry and clean. There must be no lice or red mites waiting for a chance to multiply. The floor should be wind and rat proof. The window arrangement of the brooder house is less important. The brooder should be placed where the sun of noonday will not rest on it. The morning or afternoon sun will do all the good needed and not over-heat the brooder when least desired.

It should have at least two warm compartments, one that can be heated to ninety degrees and serve for a sleeping room, the other to be warmed to over sixty degrees of temperature and be used for a retiring place from the cold of the brooder house. If the "mother" that hovers the hot room is round and has a border of woolen fringe, it is so much the better. The opening and airing of the brooder during the sunny hours of the day will be conducive to good health.

The time to start the heat in the brooder is when the chicks begin to hatch in the incubator. The whole brooder needs to be warmed. Plan to run the brooder lamp at least two days before putting in any chicks, then there will be less danger of the heat running down the first night and the chicks piling up and taking cold. The lamps should not be so placed as to get over-heated.

If there is a water tank on lamp, keep it filled. The better the oil used the less crusting of the wick and the less danger of over-heating the brooder. Fill the lamp when you please, but trim the wick toward night, so that the last visit of the day will show you that the light is likely to go through the night safely. Make sure that the ventilating holes are uncovered, so that the circulation of pure, warm air is not obstructed. The best chicks are never raised in air that is breathed and rebreathed.

The chicks are now thirty to forty hours old and can be moved from the incubator to the brooder. They are crowding to the glass of the incubator and picking at it. The brooder has been warming up for two days; the thermometer in the "mother" indicates ninety-five degrees. Cover the bottom of a basket with warm chaff or cloth and have a woolen cloth cover to put over the chicks when carrying them. Open the door of the machine, remove the chicks quickly, cover and take to the brooder house. Put the chicks inside the "mother" and close the brooder. Do not put over fifty chicks into any single brooder made. This is all that will do well in a flock.

Newly hatched chicks should not be fed for thirty-six hours (or more) after leaving the shell. For their first feed nothing is better or safer than chaff from the barn. In this are seeds and leaves that require some effort to find. Feed very little at a time and every two hours the days of the first two weeks, then increase the length of time to three hours. Water should be kept before the chicks at all times, also a dish of chicken grit. When the chicks are three days old begin to feed a baked mash. This is made by mixing three parts corn meal, three of bran, one of meat meal (all

by measure) with hot water or milk and bake in a slow oven for two hours. This "cake" is crumbled and fed in the litter of the brooder. Alternate the feeding of cake with dry grain.

The first feed of the day may be cake, the next cracked wheat, then cake, then hulled oats, then cake, then cracked corn, etc. Vary the feeds from day to day. Always keep the birds slightly hungry. Green food adds to the health and growth of brooder chicks. This can be carrot tops, lettuce, cut cabbages, steamed cut clover or cut onions. Clover meal in the mash will give green food in a convenient form. An occasional feed of finely cut green bone will be good after the second week, but must be offset by reducing the meat meal in the mash. The early weeks of a chick's life should be used in making size and frame, rather than weight. Feed well, but do not over-feed. Just as soon as the chick learns to scratch give all dry grain in the litter of the floor. This gives the necessary exercise and helps along the appetite and digestion. The active chick is seldom sick and does not show signs of leg weakness.

When the chicks are a week old they can be let out onto the house floor to eat their mash, but see to it that they know their way back to the brooder. Do not let these early chicks go outside the house. Open the window and door to admit fresh air on pleasant days. After the first few days let the brooder thermometer alone. Watch the chicks rather than the temperature. When the heat is right you will find the chicks at the fringe of the "mother." If they are much inside of it the heat is not enough. If they lay outside of the hover, you are running the lamp too high.

Until five weeks old there is little change in diet. The chicks are to be fed little and often. There should be variety in the articles of food from day to day. Once a week the chicks will appreciate a feed of raw meat. A little waste from the table of muffins or corn bread will make the chicks happy. Dry feed will eliminate much of the diarrhoea. Keeping clean the brooder and supplying fresh air to the mothered chicks will lessen the number of colds, whether of the nostrils or bowels. Lice must be kept under or the profits will be very small. Old houses or brooders that have ever been inhabited by red mites must be absolutely free of them before putting in a chick. —Commercial Poultry.

HENS THAT PAY.

Hens may be divided into three classes: Those that are not worth their keep; those that produce enough to cover the cost of handling, and those that more than meet the expense of money and time necessary to make them worth while. Of the three classes the last is the one that we all desire and the one that we can have if we are willing to pay the cost.

What is necessary to secure birds that pay? It takes more than money to do it. You may be able to buy profitable birds, it is another thing to make them profitable after they have been purchased. Not only must you have the right kind of hen, but you must use time and thought in caring for her to make her of the "paying kind."

The paying hen is usually hatched from a paying strain. The paying hen that comes out of a flock of good-for-nothing birds is seldom met and is not worth hunting for. To find good hens in poor flocks takes time, and time means money; it takes born hen sense to produce a flock of paying hens. It takes a very little neglect to send a good flock to the class of non-paying birds.

Paying birds are a delight. You like to show them to your friends; you like to linger in your description of what they are and what they have done for you. This class of birds, because they pay, receive thought and attention from you. You gladly take care of them; you are willing to properly mate and feed them; and you look for fresh blood to improve them.

Paying birds never make up a large part of your flock when you sell the cream of the chicks every year. Money-making flocks are made up of the best you raise—always letting the second quality go to market.

Paying birds live in houses free from vermin; they are usually supplied with pure air and water. They get feed that is needed to bring the profit to the proper point. Cheap feed, because it is cheap, never helped to produce the paying hen or kept her running to the nest.

Hens that pay can be yours if you are willing to do your part. Hens that more than pay, those that yield splendid profit, are what the world is asking for, is looking for, is demanding. Are you to be among the breeders who will fill the orders for this kind of birds?

It also pays to breed fancy birds. No one need fear that the breeding of that class of birds will be overdone. The "short term" fancier and the demand for good birds by those starting in the business will keep up an active demand for high-class stock for many years to come.

The small per cent. of really high-class exhibition birds from the average mating will also help keep the market alive. From five to ten per cent. of the best matings produce top birds. Fifty per cent. of any variety or breed should be sold for table use or kept for market eggs. Line breeding, a closer following of pedigrees and severe selection will improve these averages in any breder's yards.

The breeding of fancy birds present as much of an opening today as the breeding of any other class of pure-bred stock. It can be entered more cheaply, and for the man of real ability as a student of breeding, the returns will come sooner than in any other field. Hard work with the hands and good work with the head will put the breeder to the front early. There are many men who are putting the best they have in themselves into the business of poultry breeding, and they are making names for honesty and success. Stand up for fancy breeding and the business in general. There is room at the top and applied manhood can get there. The breeding of fancy poultry is a recognized calling, and many glory in it.—Farmers' Tribune.

FOR FRESH EGGS.

This is the season when fresh eggs should be plentiful. If you have hens that are not laying, well, the fault must be yours. Hens that are not well cared for will not produce eggs abundantly.

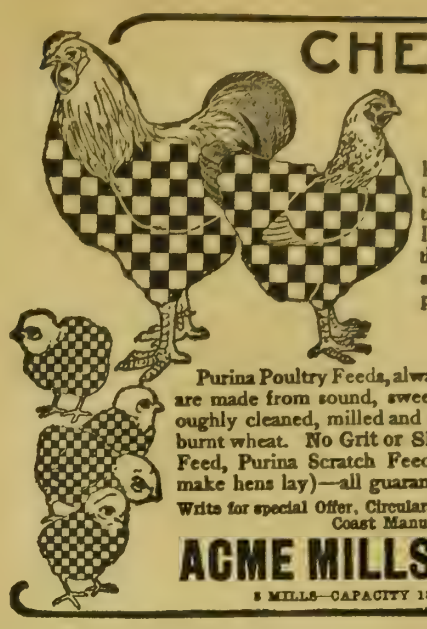
Eggs to meet the popular demand must be fresh and good.

Sell nothing but good, fresh eggs.

A wholesale firm that makes a specialty of handling eggs has this to say: "From the standpoint of wholesale shippers, we have always tried to impress upon all handlers of eggs, either dealers, merchants, or farmers, that to realize a good price for eggs they must deliver good goods. What the consumer wants is eggs that are fresh, not 'were fresh,' and in warm weather an egg that is more than four or five days old can not be called absolutely fresh, any more than a fish that is caught out of the water is fresh fish, after it has been out for the same length of time. If we could have all the eggs that we buy gathered the day that they are laid, and kept in a moderately cool, dry place and delivered to us not over four or five days old, we could realize a much higher price for them, and we believe the one great thing to impress upon the minds of the producers is care and promptness in marketing their product."

LAYING NESTS.

Good nests can be made of ordinary boxes or packing cases for canned goods, with the front cut down about two inches to make the access to them easy. These can be arranged on either side of house by puting two strips, 1x2 inches as supports for boxes to rest on. Put a board in a slanting position over the nests as a protection from sun and rain. You can put five of these boxes on either side of house. Do not nail them but just set them on the above dimensioned strips, they can thus be removed and cleaned out, white-washed, etc. Houses built this way can be moved from one part of run to another very easily.



CHECKERBOARD CHICKENS

Why are you raising Chickens? For your health or to make money? If to make money then you must feed right. Mixing a few things together doesn't make a Poultry Feed. It is a scientific proposition and requires a thoroughly equipped mill to grind and clean and blend grains and seeds in just the right proportion for baby chicks or laying hens.

The Purina Checkerboard Bag

Purina Poultry Feeds, always in checkerboard bags, are made from sound, sweet grains and seeds thoroughly cleaned, milled and screened. No smutty or burnt wheat. No Grit or Shell. Purina Baby Chick Feed, Purina Scratch Feed, Purina Egg Food (to make hens lay)—all guaranteed.

IMPROVEMENT OF CATTLE.

(Continued from Page 519.)

uously in the production of breeding stocks. From the breeder's standpoint, each succeeding cross becomes less and less satisfactory. Cross-breeding is more justifiable among those classes of animals such as swine, which reproduce quickly and abundantly, and mature early, for in such cases it is easily possible to return to the original types for breeding animals. While we must admit that cross-breeding has rendered valuable service, in the form of single out crosses, in the formation of new breeds and types, still, it should not be practised among cattle on the ordinary farm for three reasons, viz:

(1) It would tend to destroy the identity of breeds; (2) the results are in many cases uncertain; (3) it might render pure-bred females less capable of breeding true to type.

In-and-In-Breeding.

Because of the fact that the several terms used in connection with the breeding of various related animals are always not properly used, or understood, it may be well to define them.

(1) In-and-in breeding implies the mating of animals closely related, for a number of successive generations; it includes close relationships and continuous repetition. (2) In breeding implies the mating of related animals in a single instance, or at intervals among the generations, without much regard for the closeness of the relation ship. (3) Close breeding merely implies that closeness of relationship existed between the animals mated. (4) Line breeding implies the breeding of animals within members of one family, or one or more related families. It is virtually a continuation of in-and-in breeding, the relationships being less close.

It is astonishing the extent to which in-and-in breeding and in-breeding are allowed among the common stocks of the country, and this, too, by some persons who realize fully the seriousness of the practise. It arises, of course, from the selection of sires from among the offspring of the herd; in some cases, it may be due to a lack of means to make a suitable purchase, but in general, it is due to carelessness or indifference. When in-and-in breeding is carried to far, the following evils are likely to result, viz.: loss of size, delicacy of constitution, impaired reproductive powers, and in fact general deterioration.

The practise of in-and-in breeding, and in-breeding, should not be denounced entirely, for they may become useful factors when employed by those skilled in the art of breeding; they must almost necessarily be used in the formation of new breeds, where it is the aim to fix new characters in animals, and secure uniformity and permanence in the transmission of the same. But, on the other hand, the improver of common stocks has no occasion to resort to close breeding. He is not going to become a former of new breeds or types, but is going to improve his common stocks through upgrading, in which he will rely solely on the prepotency of the sires chosen to work the transformations by which each succeeding generation will be brought more near to his own standard of excellence.

'If a pure male were to beget progeny from females of the same breed, which bear a close resemblance to the male parent, this result would be a stronger evidence of prepotency in the male, than a similar result produced by mating him with females of mixed breeding, since the resistance to modification in the progeny of the females in the first instance would be stronger than resistance to the same in females in the second instance." This quality in a sire is one of the most important factors stimulating rapid improvement in any process of up-grading. It is more important in the sire than the dam, as the effect on the sire's side is more far-reaching. Probably one of the most difficult things in animal-breeding is to determine whether a sire is possessed of prepotency or not. It is conceded by some, that prepotency is the result of certain lines of breeding, and that certain visible characteristics must accompany it. The following are some influences tending to produce prepotency, viz.: (1) duration of purity of breeding without admixture of alien blood; (2) uniformity of type and results from animals in pedigree; (3) inherent vigor of type, race, or individual; (4) line breeding. To illustrate the first point; it is well-know that it matters little with what breed of type a Holstein bull is mated, the offspring is almost sure to resemble the sire markedly in characteristics, and particularly in color; it is doubtful if any breed of cattle has been bred pure for a longer period than a Holstein, and the inherent vigor of the breed is indisputable. The ability of the Hereford, also, to transmit uniformly its characteristic color markings, especially the white face, is an evidence of prepotency, the result of a long period of pure breeding. In selecting a prepotent sire, it is well to study the pedigree and ascertain as far as possible what is known relative to the performance of the ancestry as breeders, for an animal the progeny of prepotent ancestry, is certainly likely to be more prepotent than an animal whose ancestors have not been prepotent.

Illustrations Nos. 3 and 4 must be considered not singly, but as a group. The upper row of illustration No. 4 represents two pedigreed Holstein cows and, below, their calves sired by the Holstein bull, Count Colantha Alban 25148, shown in illustration No. 3

Bees and Their Care

COMB HONEY PACKAGES.

BEFORE the section box came into use much of the comb honey was produced and sold in five and ten pound boxes. These had glass over one end, two or more augur holes in the bottom served as an entrance through which the bees worked. This was a poor contrivance as it did not allow enough freedom of passage between the brood chamber and the surplus department.

These boxes were in common use among advanced beekeepers from 1860 on until the section box drove them out about twenty years later.

The first sections were made to hold about two pounds of honey and were a decided improvement on the other method. They admitted of better communication with the brood chamber and it was found that at least double the amount of honey could be secured in a season by this method over that of boxes with augur hole entrances.

In order to build comb and store honey above the brood chamber there should be as little hindrance as possible to the admission of the bees and the warm air of the lower hive. No comb building can be done until there is a cluster of bees and a proper degree of heat.

The old-fashioned two-pound section was a good package and beekeepers would have done well to have refused to use anything smaller, but, under the plea that the trade called for a one-pound section a change was made to the latter size and in time it became the standard and the two-pound section went out of use.

But this change resulted in cutting the surplus department up into small compartments, again hindering comb building to a certain extent. It is well known that a loss in yield resulted from the use of the smaller section. However, there was no movement toward a better arrangement until the price of sections doubled within a few years. This increase in price was the result of two causes, first, the growing scarcity of basswood timber from which they are made, and, second, an agreement or understanding between the manufacturers which amounts to the same thing as a trust.

The Texas beekeepers were the first to make a change with a view to discard the one-pound section. A few years ago some of them began to produce what they call "chunk honey." The honey is taken in ordinary brood frames either shallow or full depth which are supplied with narrow starters only. Thus the combs being built entirely by the bees have no mid rib of foundation as is the case with section honey. This chunk honey of Texas is cut out of the frames and packed in tin cans, extracted honey of the same grade is poured in to fill up all spaces.

But recently an article by a Russian beekeeper, Mr. A. E. Titoff, in Gleanings in Bee Culture, has set me to thinking and I would like to set other beekeepers of the North West to thinking along the same line.

Mr. Titoff describes the comb honey packages that are used successfully in Russia. The honey is produced in ordinary frames and then cut and packed for sale in shallow tin boxes that hold a single comb of one or more pounds. The combs are cut to fit the boxes by special tools made for the purpose. Anyone can see that there would be but little leakage from the combs and but little trouble from granulation.

In Russia these boxes are covered with pretty litograph pictures right on the tin, showing bee hives and flowery meadows with bees flying round. Then, in large ornamental letters the kind of honey contained. It seems to me that would make the package more expensive than necessary. The boxes could be made from lightweight tin, and neat labels pasted on them. These labels would contain the beekeeper's address and guarantee, description of the honey, etc. This would make a neat, tasty package. The boxes could be placed in the grocer's showcase with the lids thrown back disclosing the surface of the honey comb. They could be crated for shipment, and would take a lower rate than section honey and suffer nothing from breakage. If saved, the boxes could be used for honey the second time. If not used again for honey it could be used for some other purpose. Sections are never used but once. The production of comb honey in one pound sections involves an immense amount of labor, and pretty well skilled labor at that.

Then there is this in favor of producing honey in the large frames: At least a third more can be produced with the same force of bees. I for one would say, let the expensive and troublesome pound section be done away with if we can adopt a method that will save labor and result in larger yields of honey.—In Sentinel.

ABOUT BEES.

There are 5000 bees in a pound.

The orchard is the best place for the apiary.

Queenless bees nearly always build drone comb.

Blame yourself if you are not making a success with bees.

We doubt if there is a better honey plant than alsike clover.

A comb building colony is ordinarily a strong colony.

Colonies with young queens are less inclined to build drone comb.

From the time it is hatched until it becomes matured, the bee is 21 days old.

It is estimated that it costs the bees 10 pounds of honey for every pound of comb.

A thin-bladed screwdriver, 12 or 15 inches long, is useful for forcing frames together, before wedging up.

The progress apiculture has made during the last period of years is mainly due to the movable comb hive, but it should not be forgotten that this great invention is, or should be, only an auxiliary for the accomplishment of certain ends. Combs should be undisturbed except when strictly necessary. It means a loss to the bees and beekeeper every time the latter interferes with the former's affairs. The condition of a colony may often be correctly judged from the behavior at the entrance. Always observe, seldom operate, should be the beekeeper's motto.—Exchange.

About 5000 species of bees are said to exist. Bees stand in social and constructive ability at the head of the insect kingdom and it may be presumed that this is why they exist in such numbers and variety. It is probably true, as we are told by scientists, that we can never fully realize the important influence which bees exert upon the plant world by pollinization.

In a good honey season Southern California will produce approximately 250 carloads, San Joaquin valley sixty-five cars and Inyo county eight cars, all of fifteen tons each. A carload of extracted honey is 250 cases and a carload of comb honey in 1200 cases, both about 30,000 pounds net weight of honey.

SPRING WORK.

Henry Ward Beecher edited an agricultural paper during a portion of the time he was stationed at Indianapolis, and had this to say in an article on "Spring Work on the Farm:"

"Seeds are sprouting, trees budding, flowers peeping out from warm nooks. Everything grows in springtime. Youth is springtime, habits are sprouting, dispositions are putting out their leaves, opinions are forming, prejudices are getting root. Now, take at least as good care of your children as you do of your farm. You break a colt, and break a steer, and break a heifer, and break the soil, and if you won't break your children, they will be very apt to break you—heart and pocket."

Never fret, repine or envy. Do not make your yourself unhappy by comparing your circumstances with those of more fortunate people: but make the most of the opportunities you have. Employ profitably every moment.

The Angle of a Hoe

Grasp a Keen Kutter Hoe as you would in the field—better yet, put one to actual service, and see how well it fits its job. The angle of the blade is *just right.* If you strike at a weed, you are sure to cut it—if you "hill" a plant, it carries a full load of earth each stroke and does it all in the *easiest position* you can assume.

KEEN KUTTER

hand tools for the farm—Forks, Hoes, Rakes, Scythes, etc., are fitted by *model* and *temper* for great service and long wear.

Keen Kutter bench tools are the best to be had. The list includes Planes, Saws, Axes, Hatchets, Hammers, Adzes, Augers, Drawknives, Chisels, Gouges, Bits, Braces, Gimlets, Squares, Bevels, Files, etc., besides every possible tool and cutlery for the household. Look for the trade-mark—it guarantees *quality.* If not with your dealer, write us.

No Live Stock Diseases

IN ALBERTA, Canada there are no live stock diseases such as hog cholera, black leg, scabies or other contagious or infectious animal plagues.

If you are a farmer you know what a difference it would make in your annual profits if you did not have to take losses of live stock from disease into consideration.

Sunny Southern Alberta is the finest stock country on earth because cattle, hogs and sheep can be produced cheaper there than anywhere else, and because there is a good market right at the door of the stock raiser.

Since the great Canadian Pacific irrigation project has been started the farmer who likes diversified farming will find a paradise in Alberta as he can raise all kinds of live stock at the lowest cost and he can produce practically all kinds of cereals and vegetable crops at the same time his live stock is growing and developing.

On the great Canadian Pacific irrigation tract hundreds of farms have been laid out a portion of which are under irrigation and a portion of which can be devoted to the live stock industry—In other words you can buy a natural range for live stock which produces the finest grass to be found anywhere and you can raise on another portion of your farm forage crops for winter feed, sugar beets, wheat, oats or any other vegetable or cereal, you desire to cultivate.

If you desire to engage in the dairying business you will find conditions perfect in Alberta—The government operates the dairies and pays the farmer for his cream every cent there is in it, simply retaining enough to operate the dairies and to pay for the cost of marketing the butter.

Of course, if the farmer desires to make and market his own butter he is at perfect liberty to do so, but the government can make it and market it at better prices and at lower cost than the farmer possibly can and the additional profit goes to the man that milks the cows.

Land can now be bought at prices so low and on terms so easy that no man should be without a farm. If you want to know how to see Alberta at the least possible cost, and how to secure lands that will make you independent in two or three years we will be glad to tell you—Write for full information to

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Indigestion in Calf.

What was the matter with this calf? When four days old, I took the cow, drove her and the calf one mile, and let it suck my fingers the next morning until it had swallowed three pounds of milk, a mixture of its mothers and that of other fresh cows. That night it seemed to prefer to sleep than drink. It would not suck my finger. The next day I saw that it had passed a little bloody dung. Its mouth was cold. I tried to get it to nurse its mother, but it wouldn't stand up to suck while I held it. I next gave it a teacupful of raw linseed oil by the means of the bottle, and in about an hour it was dead. Post mortem showed that no milk had gotten into its lungs. The paunch was filled with curd and watery fluid with a decided acid smell. The abdominal cavity had a watery fluid in it around the digestive organs.—H. M. Mc.

Calf troubles need prompt handling or the patient is dead before we know it. In raising calves by hand rennet tablets are invaluable. The kind that come for junket, can be purchased at any drug store for ten cents a package, will answer just as well as the more expensive tablets used by the cheese makers. Mix the tablets with a little warm water and add to the milk just as the calves begin to drink it. Indigestion is quickly checked when this is used and the calves do not get off their feed.

If the case had occurred here we would first have removed the calves to a new place, leaving the sick one where it was. At once two raw eggs would have been put down the calf's throat and a warm woolen blanket wrapped around him. If he was lying down then hot water bottle under the blanket and along the spine to get him warm as fast as possible. In two hours a pint of hot milk with a tablespoonful of extra cream in it with the rennet tablet should be given. In two hours repeat the eggs, and in two hours more the hot milk. If the calf has rallied, and they usually do, readily under this treatment, make a blanket and sew it on him so he can not get cold. Give a dose of the hot milk four times a day mixing into it the two eggs, as soon as the calf grows strong it can be gradually worked back to the regular feeding time of the other calves. We have found it well to use a little dilute boric acid on the naval cords of all the newly dropped calves and colts. Clean and whitewash the stable before putting any other calves in it after having had a case of the scours.

Scrofula.

I have a heifer calf five weeks old that has some small sores breaking out on the skin, which dry up and the hair comes off with the scab. Its ears are now almost entirely naked. I feed it as I feed all my calves, ten days full milk, and at three weeks old it gets straight skim with a little oil-cake meal jelly added.—W. B. Delsur.

This calf may be scrofulous. It sometimes happens in well bred cattle. Better remove the well calves from this one and if is a contagious trouble they will be safe from infection.

Make an emulsion of melted soap and hot water adding coal oil to it with a few drops of carbolic acid. Mix until it does not separate. Usually a cake of soap and a quart of oil is about right. Wash the spots with this hot and cleanse them thoroughly. Then rub on the following: Lard, three ounces; Sublimed sulphur, one ounce. Bicarbonate of soda, two drains. Vaseline can be used instead of lard or any clean grease from the kitchen that is free from salt. Bicarbonate of soda is the baking soda used in the kitchen so this can be prepared at home. If the calf is in good condition I should cut out some of the oil meal and give it instead a gruel of bran and rolled barley, about a teacupful each meal. If it is thin add a little more of the gruel and give it a junket tablet to aid in the digestion of the food. Whitewash surroundings and burn up bedding that is around. Use carbolic acid or some corrosive sublimate tablets in the white wash to purify the surroundings.—M. E. S.

Holsteins Have Horns.

Do thoroughbred Holstein cattle have horns or not? This is to settle a very warm argument.—A. M., San Francisco.

The Holsteins have horns naturally. The dairyman removes the horns to help him, as the cows can be placed in closer quarters if they have no horns. It also saves the injury that they can do to each other by hooking the udder. Feeders dehorn the steers they are fattening and think it pays, as they are more docile. Also in shipping more dehorned animals can be put into a car. The dehorning may be done while the calf is very young, when a week old, with caustic potash, or when the animal has reached maturity the horn may be removed with a clipper designed for the purpose.

There are several strains of cattle that have been formed by breeding together the muleys, also a strain of Jerseys, and also the Polled Angus, though it is said that sometimes even they revert and show horns. A bull dehorned after maturity, is disarmed and rarely regains the confidence in his abilities to be master of everything in sight.

A little girl was looking at some cows and suddenly ran to her mother in fear. The mother said: "Why, my dear, the cows cannot hurt you, they have no horns." "Yes, they can bump me with their pompadours."

A dehorned bull can inflict severe injury with his head.—M. E. S.

Sore Leg.

About a week ago my cow walked lame. I found her left hind leg was sore just above the hoof. I put some liniment on that had turpentine in it, but that hurt her. Have been bathing it with hot water and using a little carbolic acid in the water. The leg swelled up some, but not a great deal.

After a few days the right leg got as bad as the other, now she can hardly get around at all.—Subscriber, Anderson.

The causes may be insect bites, or it may be alkali, particularly if the cow can stand in water and then in alkali dust. Wash the legs with soapy warm water containing twenty drops of carbolic acid to gallon. Then grease well with carbolized vaseline, or use an ointment of one dram of oxide of zinc to one ounce of lard. Keep the cow in a place free from dust until the trouble disappears.—M. E. S.

Lumps on Leg.

I have a four-year-old cow that has a small sore on her knee. It has been there some months. About two weeks ago lumps, some of them the size of a walnut, began to form all along the vein on the outside of the leg. She does not seem sick, eats well, hair is glossy, and seems not to mind the lumps which are not sensitive to the touch.—A. J. R.

This seems to be a local infection resulting from the sore on the knee. The information is hardly full enough to be positive. Is the character of the sore hard and dry, or soft and moist? A careful examination may show a splinter under the skin or some other foreign substance acting as an irritant. The sore is evidently the cause of the lumps, and we would try to heal that first. Leave off the liniments. Wash the sore with a weak solution of carbolic acid in water with castile soap, using the water hot enough to be comfortable to the cow.

If it discharges from under the skin, inject with a 10 per cent. solution of hydrogen peroxide. Apply to the sores and lumps; brown citrine ointment mixed half and half with lanoline; apply twice a day with friction. —M. E. S.

Garget.

My cow has a sore teat. A hard lump is in the upper part of the teat and feels something like a compact mass. Some milk comes out of the teat and a little lumpy substance. I think her udder is a little bit inflamed.—A. B. G., Ukiah, Cal.

A touch of garget, is the trouble; avoid dry feeds, give her grass and a good physic, using a pound to a pound and a half of epsom salts with a tablespoonful of ground ginger. Bathe the affected parts with hot lard or hot water and after a half an hour of gently rubbing, bathe the part with spirits of camphor. If the case is a bad one, refer to the Cultivator of last month for full directions for formenting the udder with hot flannel.—Mrs. M. E. S.

Probably Garget.

I have a fine heifer which calved about two weeks ago, she seemed to do fine in every particular, except we find after the milk stands a short time there is a little settling in the bottom of the vessel which we take for blood.—W. W., Santa Cruz.

Bloody milk comes from rough handling of the udder, from blows, from sexual heat and garget. It is safe to begin by giving the cow a dose of epsom salts, one pound to a half gallon of warm water adding a heaping tablespoonful of ginger. Bathe the udder gently with weak hot vinegar. Milk gently and thoroughly. By milking one teat at a time and putting the milk into separated marked pans the quarter affected can be located and milked with greater care. Avoid any irritating foods, giving bran and good hay or if in pasture confine her to that which contains no weeds.—M. E. S.

Grasshoppers.

We are suffering form a plague of grasshoppers; which threaten to destroy all our crops. Can you tell me any way to treat our garden to prevent them attacking it?—P. N. W.

There is but little hope of "preventing them attacking" only to slaughter before that stage of the game.

In a short time, possibly next week, the Cultivator will have an extended article on latest suggestions for handling the grasshopper question.

Too Rich.

I am informed by my customer that he can not use my eggs because the yolk of the eggs is two yellow, and that they don't look good. Now the chickens are all in good healthy condition and they have plenty of green range, plenty of grain, but no alfalfa. —P. G.

The trouble with your hens is they have been fed too rich food, too much meat or grain, or both. Feed lighter of grain and more green food. A good plan is to get some good egg food manufactured by some reliable firm and feed according to directions. I don't mean a tonic, but a well-balanced egg-ration. You will get more eggs and you will not be bothered with the trouble of which you speak. —F. H. T.

Apricots, Morning Glory and Pears..

Is it advisable to cut back old apricot trees as they seem to have too much tree and never much fruit? They are the Royal. At what time of the year?

How can I kill the morning glory (wild). It grows about 2 feet high and is dark green and resembles the cultivated morning glory in flowers and shade of leaves.

Will pear trees bear when they are grown from the suckers or shoots springing from other trees? And can they be grafted at this time of the year?—Harry E. Brockman, Corona.

Trim your apricot trees so as to retain the shape of the tops. Select main branches so as to accomplish this, trimming them up to straight stems. Do this in the winter time.

Morning glory can only be kuled by cutting it off under the ground often enough to prevent its getting through the surface. Every green leaf it makes gives it renewed vigor. Make it a rule to do this often enough to accomplish this, and in about two years you will have killed it out; it cannot live over two years unless it makes a green top occasionally.

Pear trees cannot be grafted well after they have leafed out. The proper time is before or at the time the buds begin to open.—J. W. M.

Outdoor or Indoor.

Will you kindly express judgment as to the comparative merits of outdoor and indoor brooders for chickens; particularly in regard to the vigor of chicks raised by the two methods.—Robert J. Teall.

There is no difference in the indoor and outdoor brooder so far as raising chicks is concerned or there should not be. In an outdoor brooder the lamp is better protected so it will not blow out; also the brooder is made so it will offer protection to the chicks in a rain, having a water-proof roof. The indoor brooder is not made storm-proof, and as the name signifies is made to be used in a house or under a shed. Either, if run properly, will raise strong, healthy chicks.—F. H. T.

Rubber Boots.

What can I put on my rubber boots to keep from leaking?—J. M. Arroyo Grande.

There is but little hope for leaky rubbers. Better buy new pair of high grade. It's barely possible that you can take some of the thin rubber of the inner tubing of your boy s bicycle and with a good rubber cement which is sold at nearly every store, patch up the boots for a time, but "mending rubber" is a makeshift at best.

A HINT FROM COMMISSIONER PEASE.

San Bernardino County Horticultural Commissioner Pease, gives us the following valuable hint:

"It has been stated by some ranchers who are at present troubled by the cut worms that they will not again sow peas for cover crop because the cut worms breed in the peas.

Cut worms breed as well on many kinds of weeds, but it is only necessary to have the cover crop plowed under before April 1st, to be secure against the cut worms.

The Red Spider is again appearing in threatening numbers on Citrus trees, and need attention to prevent damage.

This may be termed a Red Spider year."

SCIENTIFIC FARMING.

In the days of our grandfathers it did not matter so much that farmers gave little heed to the science of agriculture. They had land to spare, and taxes were low. They and their sons did most of the "plough deep and rough," and let nature do the rest.

The case is different now. Land is scarce and costly. Taxes are high. Many of the boys go away to the cities to seek their fortunes. Help must be hired, and wages are an item. All the expenses of living have greatly increased. The children must be educated. The home must be furnished.

The great matter is that the soil has lost its primitive richness. Nature must be helped. The farmers of Germany and France long ago learned how to make the most of every square yard of land; not only by a perfect system of drainage, and scientific rotation of crops, but by the exact science of fertilizing. American farmers are just beginning to appreciate the possible fertility value in each acre of soil.

Many of the greatest scientists in the world have made exhaustive studies of soil enrichment; and they have all come to one conclusion on the special need of worn and tired soils. The first vital quality that is exhausted from the soil is nitrate. That element must be put back into the soil.

Farmers only need to remember that 100 pounds of nitrate of soda, enough for a whole acre of land, costs less than $3.00 They can see whether it pays. That is what science can do for them. Any furthur information can be had by writing to Dr. Wm. S. Myers, John street and 71 Nassau, New York, N. Y.

Don't Feed

the little chicks anything for the first twenty-four hours. Then feed them dry.

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seeds, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keep it, and will not get it, send $3.35 for 100 lbs., freight prepaid by us to any point in California.

Are your fowls a little off—don't you want to tone them up?

West Coast Poultry Tonic

will do it sure. It is one of the greatest cures for ROUP and all kinds of colds.

Hen Fruit Pays—if you want more, feed

Egg-More

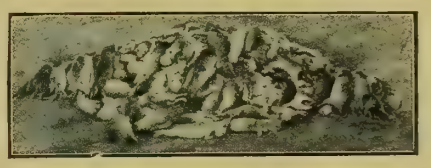
That highly nitrogenous poultry food, rich in protein, to keep the poultry in good health, and enable the hens to convert the surplus aliment into eggs. Just the right addition to a good grain ration.

West Coast Lice Killer and Killamite (powder)

are most effective pest destroyers. Nearly all the diseases of poultry may be attributed to lice and mites. Don't let them get the best of you. Get the best of them. And did you know that Killamite is just as good for killing plant insects without harm to the plant. Testimonials of public gardeners and others. Try it on your roses. 50c sifting cans by mail if your dealer won't get it for you.

West Coast Poultry Foods and Remedies

are the best made and, quality considered, the cheapest. If your dealer doesn't sell them, send to us. Booklet free. Send us names of 12 persons keeping poultry and we will send you free "The Poultry Manual" by those high authorities F. L. Sewell and Ida E. Tilson, profusely illustrated.



This is a photo of 201 Gophers killed in one day on a 10-acre field with one bottle of

BILLE'S GOPHER POISON

Not one of the ordinary poisons, but in a class by itself. Endorsed by Agricultural colleges and Experiment Stations. Has had greatest success in the Middle West. The secret being that it is most attractive to gophers, squirrels, etc., and sure death to them. It gives the grain a glossy coating, retaining the poison for weeks. Hundreds also die in their holes by eating it there. We have bought the patent right for this section and are selling at the eastern price, lower than the ingredients can be bought at a drug store. Money refunded if not as represented—so printed on the bottle. If your dealer does not keep it sent $2.50 for two bottles, express prepaid by us—not less than two bottles.

Confident that a trial will prove beyond question that the best condition powder made is

West Coast Stock Food

We will send to new customers one 25-lb.

$3.00 PAIL FOR $2.00

or one 50-lb. $5.75 double sacks for $3.50, and will prepay the freight to any point west of the Rockies. Not more than 50 lbs. to each one, and we reserve the right to withdraw this offer without further notice. No cheap premiums, no gaudily colored pictures, but a legitimate business offer to induce a trial, hoping to add many steady customers. We are charging up the difference to our advertising account, feeling sure that a trial of the goods is the very best advertising.

No strings to this offer. Just send us your name, the freight station to whch you want the goods shipped, mention this paper, and we will do the rest. Send money order or check with your order, and if every thing is not exactly as represented your money will be refunded. The First National Bank of this city, or Bradstreet's Agency, or any leading firm, can inform you as to our reliability. WEST COAST STOCK FOOD has for many years been a standard condition powder in this section. PEOPLE WILL TALK.

You may get through the world but
'twill be very slow
If you listen to all that is said
as you go;
You'll be worried and fretted and
kept in a stew
For meddlesome tongues must
have something to do—
And people will talk.

If quiet and modest, you'll have it
presumed
That your humble position is only
assumed.
You're a wolf in sheep's clothing,
or else you're a fool;
But don't get excited—keep perfectly cool—
For people will talk.

And then if you show the least boldness of heart,
Or a slight inclination to take your
own part,
They will call you an upstart, conceited, and vain,
But keep straight ahead—don't stop
to explain—
For people will talk.

If threadbare your dress and old-fashioned your hat—
Someone will surely take notice of
that,
And hint rather strong that you
can't pay your way;
But don't get excited whatever
they say—
For people will talk.

If your dress is in fashion, don't
think to escape,
For they criticise then in a different
shape—
You're ahead of your means or your
tailor's unpaid;
But mind your own business, there's
naught to be made—
For people will talk.

Now the best way to do is to do as
you please,
For your mind, if you have one, will
then be at ease.
Of course, you will meet with all
sorts of abuse;
But don't think to stop them—it's
not any use—
For people will talk.

A PANE OF GLASS.

"I'M sorry, Fred, for I like the girl, but I can't have this pilfering going on. The best thing will be to discharge her at the end of the week. This stealing has been going on for a month now, and as far as I can find out she is the first one here in the morning and alone long enough to help herself. I have noticed, too, that she has a number of trinkets lately quite out of reach of her salary."

Fred bit his lips and was silent. It would have done no good to have told his father that he had given the trinkets, conveyed in such a way that she should not know the donor.

He had been only waiting for a favorable time to tell her his sentiments, and now she was threatened with disgrace.

"I'll stake my life, father, that she hasn't a trinket about her but what is honestly come by," he exclaimed, after a moment's embarrassed silence, "and that she is a thoroughly honest and trustworthy girl. Don't discharge her this week, father. Give her—give me one week more, and let me see if I cannot discover the thief. I promise that if I find it is indeed she I will not try to shield her. But let me have that much time to try to discover the real culprit."

"I don't see how you are going to do it," replied Mr. Adams, looking around the apartment. "There is no way that I can see but getting here ahead of the thief, whoever it is—and, of course, the money will not be taken with you looking on, and there is no way for you to conceal yourself in the room here. You know I have been accustomed to leave money in that drawer, for the convenience of giving change if it should be needed, before I get down in the morning, and nobody knows but you that I am in the habit of counting it every night before leaving, and that for the last month it has not balanced with the cashier's account, but constantly shows a deficiency. It must be taken in the morning, before we get here, and Miss Allen is, as she has said herself, the first one here—indeed, she has a key of her own, so that she can get in as early as she pleases."

Fred's eyes had been roving around the room while his father was speaking. There was, as he said, no possible chance of his concealing himself anywhere in the room without making the fact of that concealment evident and thus defeating his purpose; but as he glanced over at the desk, which stood at the opposite side of the room near the window, and in one drawer of which was kept the money for such miscellaneous expenses as postage, telegrams and other incidental small expenditures, and from which sums that could not be accounted for had been missing for a month past, his face lightened. The window faced another window of a large building, the side of which was separated only by a narrow court and which was for the time vacant, and a suggestion occured to him which he seized upon at once.

"I'll admit that it does look black against her, father," he said. "But I believe I can find a way in a week's time either to vindicate her or prove that your suspicions are just, though I believe that it will vindicate her. Just let me have one more week, and if I don't discover the culprit by that time I will make no further plea."

Not only Margaret Allen, but the three other girls in the employ of Mr. Adams' photographic establishment missed the frank, bright smile and pleasant word with which his son had been wont to greet them, and into Margaret's pretty eyes crept a look of hurt surprise mingled with a deeper feeling that went to Fred's very heart. But he maintained his demeanor unshaken, meanwhile studying each face and act of the girls with a scrutiny he had never bestowed upon them before, and by night he had pretty well settled in his own mind as to the culprit, but to make that suspicion a certainty was the task that remained.

The next morning the girls were at their work as usual when Mr. Adams and his son entered the establishment. Both gentlemen looked serious, but on Fred's face was also clearly manifest a look of triumphant satisfaction.

"Young ladies," said Mr. Adams, addressing his employes. "I have rather an unpleasant subject to introduce this morning, but it is not of my own choosing and I would prefer to give you an opportunity to acknowledge your act than to charge you with it. Which of you is here first in the morning?"

"I believe I am, sir," answered Margery, to which the others assented.

"Well, I am sorry to report that for some time past I have been missing small sums of money from the drawer where I keep the change for incidental expenses and to which you all have access as occasion requires," continued Mr. Adams. "Now, I will put it to you formally, Miss Allen, do you know anything in regard to the missing money?"

"I do not, sir," she replied lifting her eyes to his face with a look of perfect innocence and truthfulness, while Fred, in his delight and joy, could scarce restrain himself from hugging her on the spot.

"Miss Wilson, do you—or you, Miss Douglass?—or you, Miss Ferris?"

A most emphatic denial was the unanimous response.

"Well," said Mr. Adams, "it seems that we must resort to some other means to ascertain the culprit. What have you to say, Fred?"

"Merely to ask the young ladies if any of them recognize any one they know in this," responded Fred, drawing out a small plate and laying it before them. There was an excellent photograph of the interior of the room, and bending over the open drawer in the desk, in the act of taking some silver from it, was the unmistakable profile, face and figure of Lottie Wilson.

With a startled cry she drew back, covering her burning face with her hands.

"If you will tell me the whole story

I will let you off with no greater punishment than being discharged from my service," said Mr. Adams, sternly. "Otherwise I shall call an officer and hand you over to him forthwith."

Overcome with terror at this threat, Lottie sobbingly confessed that she had been the thief, having coaxed the housekeeper to let her in on the plea that she wanted to get to work early, and then slipping out again and not returning until after Margery had arrived, so that if the theft was discovered suspicion would fall on her. Mr. Adams heard her to the end, then, quietly requesting her to get hat and cloak, attended her to the door and bowed her out. Then returning to Margery, who was standing a little apart from the rest, he said in a tone of more than wonted kindness:

"There is a little story connected with this discovery which there is not a fitting opportunity to tell here, but if you will allow my son to escort you to my house this evening to dinner, I will make you acquainted with my wife, and you can hear the sequel of this affair."

Margery bowed, too happy to speak after one eloquent look from Fred's eyes, and went back to her duties, with a heart bounding high. At the appointed hour Fred accompanied her to his home, where, after being introduced to his mother, who took the orphan girl to her heart and embraced her at once, they told her the story.

"The moment I looked at that window of the building opposite," Fred said in conclusion, "it occured to me that I might make use of it as a point not only of observation, but from which I could obtain a view of the place and the culprit. By investigating and experimenting I found that I could photograph the room accurately. And I had a shade put up, leaving only one pane of glass exposed, in front of which I could place my machine and do the work without being seen in return. I was there this morning by daylight, arranged my apparatus, and about half an hour before your coming the door opened and Lottie Wilson came in. I waited until she was in the very act of taking the money, as you see, and then secured my snapshot that vindicated you, my darling, and has made me the happiest man alive—all by the aid of that blessed pane of glass."

He had not intended to make his avowal of love in such a fashion, but his joy and affection burst from him simultaneously, and the next moment he had her in his raptuous embrace, from which she made no effort to disengage herself.

"Good-by, my dear daughter," Mrs. Adams whispered as she bade her good-by before resigning her to Fred's care to escort her home. "You shall be my daughter in a few weeks if I have anything to say about it."

And that she not only had considerable to say about, but said it, was evidenced by the modest but delicate little wedding that took place not long after, at which Fred and Margery were the principal parties interested, and, if their faces were any indication, the very happiest people that could be found anywhere.

HOMELY HINTS.

One of the simplest means of loosening a rusty screw is to apply heat to the head of the screw. This may be done by means of a small bar of iron being heated red hot and allowed to come in contact with the head of the screw.

A rusty nail may be drawn by first driving it with a hammer to break the crust of rust.

If your shoes stiffen after a tramp on a rainy day, wash them over with warm water and then rub castor oil thoroughly into them. This makes the shoes soft and elastic.

When a broom becomes shorter on one side, and the ends of the straws become as sharp as needles, dip it into hot water, trim it evenly with the shears, and you will have a broom nearly as good as new.

A careful housewife has discovered that common salt sprinkled over any object that is stained with lamp-black will remove the dirt if rubbed in and then removed. Several applications may be necessary.

Enamel ware that has been burned or discolored may be cleaned by applying a paste made of coarse salt and vinegar. A little vigorous rubbing will remove the ugly marks.

NURSERYMEN, EXPERIENCED IN RAISing Eucalyptus seedlings; wants position. Address, BOX 9, Del Mar, California.

TWO GOOD ENGINES.

At the reserve plant of The Times on San Fernando street, are two 50-horse-power engines which represent the most modern ideas in engine building. They are known as Western Special engines and were supplied by the Western Gas Engine Company of this city, of which W. H. Frost is president.—[L. A. Times.

The Produce Markets

Los Angeles Markets

LOS ANGELES, May 15, 1907.—A slightly weaker feeling prevails on the market, at least in most lines. This is especially true of strawberries of which an immense quantity has been forced on the market the past week. On Tuesday the finest of stock could be purchased at 4 cents, with indifferent buying for any price.

Butter.

Butter is easier though quotations are practically the same as last week.

Valley Creamery	47½
Coast fy,	45
Cooking	20

Cheese.

Cal. Young American, per lb	19

Citrus Market

LOS ANGELES, May 15.—The past week has seen a slight weakening of the orange market. The two factors principally responsible are increasing decay and the large proportion of large sizes. The percentage of off large sizes becomes larger as the season advances. But there seems to be no fear but that the 2500 cars of navels yet to forward will command fair prices.

Of Valencias, seedlings and other varieties there are about 4500 cars. These promise good returns to their owners.

Lemons are not especially strong, as the cold weather of the East causes

light demand. On the contrary the warm Eastern weather of March caused a stiff demand at a time when there was no cars to move California lemons, with the consequent high prices which caused large importations from the Mediterranean. Of these there are now on the wharves of New York, over 150,000 boxes. Some good, hot Eastern weather will have a stimulating effect on the market, and soon clean up the surplus.

Shippments of citrus fruits to this date aggregate 18,727 of which 1800 were lemons. Same date last season 19,554, of which 2058 were lemons.

NEW YORK, May 10.—The market is depressed and lower on all grades and sizes. Weather turning warm. Thirty-three oranges sold today.

IOWA AGRICULTURAL COLLEGE GRADUATE GOES TO CANADIAN COLLEGE.

Mr. V. R. Gardner, Instructor in Horticulture, Iowa Agricultural College during the past two years, has just been elected to the position of Assistant Horticulturist at the McDonald Agricultural College, St. Anne de Bellevue, Quebec, Canada.

The McDonald College promises to be one of the very foremost institutions of its kind in the world, thus the position affords excellent opportunities for promotion.

The demand for well-trained men along horticultural and forestry lines is unusually strong. During the past three weeks the head of the Department has received inquiries from three different states and one foreign country, for men to fill very remunerative positions as instructors and investigators along horticultural lines. section.

A telegram from Boston, May 15, asserts that Benjamin I. Wheeler, President of the University of California, is to retire from that institution and accept the presidency of the Massachusetts Institute of Technology.

Lake Elsinore has risen 9 feet during the past season, which is higher than it has been for many years.

Imperial Valley's latest claim is to be headquarters for a great poultry shipping industry.

A horse thief at Calexico was shot and instantly killed by Fred Vaughn last week.

1907 a Boom Year

The business of this store is increasing by leaps and bounds. We sell a far greater volume monthly than ever before. This means, surely, but one thing—our prices are the lowest to be had on dependable, high-quality merchandise. We work a little harder and cheaper than any other store, wholesale or retail. The largest buyers in this market trade here. We can sell to you if we are not already—and to your profit. Come in and talk to us about it, if you can. Our free delivery service is improved and extended to Marin County and most all of Alameda County, wherever our teams and autos can run, besides San Francisco.

Our sales must reach a million this year, and add 20,000 more customers. Your name on a postal will obtain this list regularly.

There remains only $20,000 more now of our Special Bond Issue, so if you wish any, write by return mail. They provide a high return for use of money one, two, or five years, and make the best and safest investment in San Francisco to-day. Their sale has increased our net income ten times and helps us to serve you better.

Read what this man says about Columbus Engines:

Greenleaf-Compton Company, Tropico, Cal., 4-3-07.
121 So. Los Angeles St., Los Angeles, Cal.

Gentlemen—For about four years, I have used a Columbus engine of ten (10) horse power; which has been running a 3½ Vertical pump and pumping about 35 inches water with a 90 foot lift, and when the time came to buy a new pumping plant for my ranch near Anaheim where we we shall need water for about 200 acres, I decided to have a 60-horse Columbus engine installed, and placed the order with you because I expect to have a pumping plant that cannot be excelled.

Respectfully, E. B. BARY.

This 10-horse engine is pulling 13½ horse power. We are installing a 60-horse plant for Mr. Bary, 3½ miles north of Anaheim. Come in and let us demonstrate the simplicity of Columbus Engines.

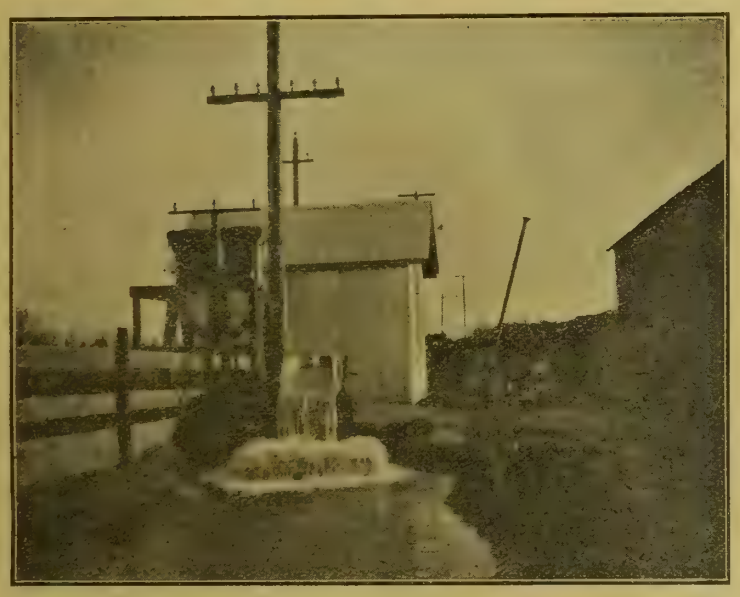
Irrigating Scenes Near City of Visalia



Pumping Plant near Visalia

Irrigating a Delano Orange Grove

TULARE COUNTY, California, is one of the largest counties of the great San Joaquin Valley—a valley that is an empire in itself . Commencing where the Sacramento and San Joaquin Rivers join to empty their waters into San Francisco Bay, and extending from the Sierra Nevada Mountains on the east to the Coast Range on the west, embracing a territory from 75 to 100 miles in width, the valley sweeps southward 250 miles, to where the Tehachapi mountains intersect with the Sierra and Coast Ranges, forming the line between so-called Northern and Southern California.

Tulare County lies just half way between San Francisco and Los Angeles, and has an area of 4935 square miles, or 3,158,400 acres. The history of Tulare county is the history of Visalia, as, in the early days, all of interest centered about the only town or emanated from it. But Visalia has had an individual progress independent of the county history; in the maintenance of schools, the organization of its churches, the formation of its lodges and fraternities, its banks, municipal organization and civic affairs. In the fifty years of its existence it has come to be one of the most thriving and prosperous cities of the valley, of great natural wealth. the possibilities of which are yet being developed.

Two Varieties of Grasshoppers

Hoppers Which Have an Appetite for Alfalfa, but Will Eat Old Leather if They Have It

Suggestions How to Control Them

THE depredation of the grasshopper has been the burden of many a letter to the Cultivator. "What can I use to poison them," "They are destroying all our crops, what will keep them off?" and other pertinent questions are constant in coming in.

The answer is not so easy, or more correctly, an answer which will suggest a method both effective and economical. At best there must be co-operation, and the isolated farmer with great expanse of uncultured lands about him is almost helpless to control the pest.

However, we have some good suggestions from an article by F. M. Webster, of the U. S. Department of Agriculture. The article applies more particularly to the alfalfa pest, but will be of value in working with any of the hoppers.

Description of Two Species.

The differential grasshopper (fig. 1) is about 1½ inches long, its wings expand about 2½ inches, and it is of a general bright yellowish-

FIG. 1.—Differential grasshopper (Melanoplus differentialis). Natural size (after Riley).
Webster, Circular 84, Div. Entomology, U. S. Dept. Agriculture

FIG. 2.—Two striped grasshopper (Melanoplus bivittatus). Natural size (after Riley).
Webster, Circular 84, Div. Entomology, U. S. Dept. Agriculture

green color. There is, however, a nearly black melanic form that does not seem to differ otherwise from the normal. The head and thorax are olive-brown, and the front wings are of very much the same color, without other markings but with a brownish shade at the base; the hind wings are tinged with green; the hind thighs are bright yellow, espesially below, with four black marks; the hind shanks are yellow, with black spines and a ring of the same color near the base.

The two-striped grasshopper (fig 2) varies in color from a dull green to a dull brown, with a distinct yellow stripe extending on each side from the upper part of the eye to the end of the wing. The male is about 1¼ inches long and the female about one-fourth of an inch longer. This grasshopper may be so easily recognized from the accompanying figure that further description is unneseccary.

Life Histories and Habits.

The eggs are desposited in the ground in masses, inclosed in more or less kidney-shaped pods, in late summer and fall, after the manner shown in figure 4, which illustrates the oviposition of the Rocky Mountain grasshopper or locust. The females seem to prefer a moderately compact, rather damp but not wet soil which is rarely disturbed by the plow or other cultivating implement. It will thus be seen that alfalfa fields throughout the irrigated sections constitute an ideal breeding ground. Winter is passed in the egg state, the young hatching in spring and reaching maturity in summer, and there is but one annual generation. Neither of the two species is migratory. Their flight is rather clumsy, and they do not remain long on the wing before alighting.

Preventive and Remedial Measures.

Preventive measures, as here restricted, apply to a period antedating the hatching of the young; while remedial measures are such as deal with

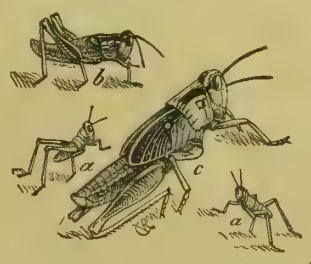

FIG. 3.—Rocky Mountain grasshopper or locust (Melanoplus spretus): a, a, newly hatched larvae; b, full-grown larva; c, pupa. Natural size (after Riley).
Webster, Circular 84, Div. Entomology, U. S. Dept. Agricul$ure

tne insects after hatching and with methods of destroying them.

While many modes of procedure have been advocated, tending to ward off impending atacks, and perhaps even a greater number of devices constructed and mixtures compounded for the destruction of grasshoppers, we will here consider only such as are readily and cheaply obtainable by the farmer and ranchman and those most practical in application.

Destroying the Eggs.

Destroying the eggs of the grasshoppers seems to be the only preventive measure that promises to be worth while atempting, except, perhaps, the destruction of the young as they are hatching. Destruction of the eggs may be accomplished by either plowing, harrowing, disking, or cultivating, in the fall or winter, all roadsides, ditch banks, margins of cultivated fields, uncultivated fields, and grassy margins along fences. In short, all waste lands that it is possible to reach in this manner should receive attention, unless it is known that no eggs were desposited there.

The soil need not be stirred deeply, two inches being a sufficient depth to accomplish the desired effect; and circumstances will probably dictate the kind of tool or tools that a farmer ought to use and where to use them. There is no doubt whatever that if this measure were put into operation at the proper time, in whatever manner is most practicable, disastrous outbreaks the following spring would be forestalled and prevented. Except in cases of isolated farms or ranches, there should by all means be concerted action in this movement.

Where fields can be quickly inundated and the water promptly run off, as is frequently done in rice fields, the young grasshoppers may be killed by flooding the field for a day or two just as the eggs are hatching. If close watch is kept to de-

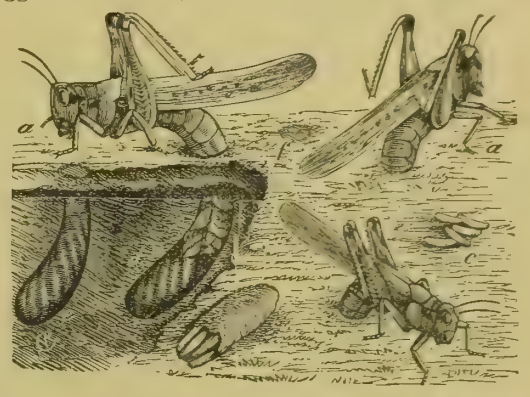

FIG. 4.—Rocky Mountain grasshopper or locust (Melanoplus spretus): a, a, a, female in different positions, ovipositing; b, egg-pod extracted from ground, with the end broken open; c, a few eggs lying loose on the ground; d, e show the earth partially removed, to illustrate au egg mass already in place and noe being placed; f shows where such a mass has been covered up. (After Riley).
Webster, Circular 84, Div. Entomology, U. S. Dept. Agriculture

termine just when the young grasshoppers are hatching, and prompt action taken at this time, much good can be accomplished; but as soon as the young begin to move about, flooding will avail but little, as the grasshoppers will climb to the upper part of vegetation beyond the reach of the water.

Destroying the insects.

Under this head will be discussed those measures which should be resorted to when the grasshoppers, having hatched from the egg, are threatening alfalfa fields from within or without, or both.

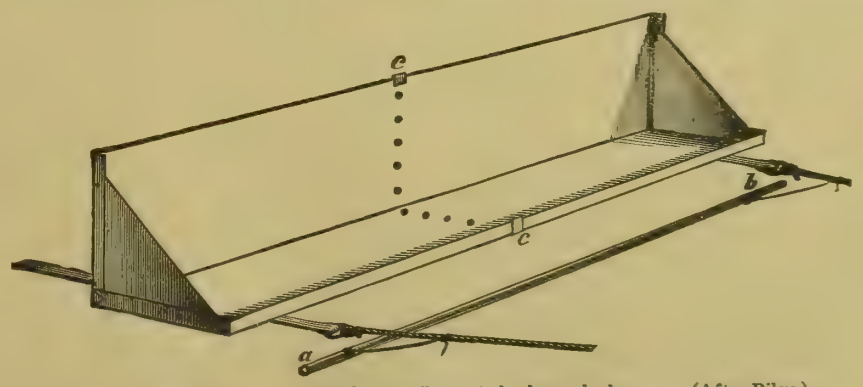

FIG. 8.—"Hopperdozer." A simple coal-oil pan, to be drawn by horse. (After Riley.)
Webster, Circular 84, Div. Entomology, U. S. Dept. Agriculture

The Hopperdozer.

On level or comparatively level land this implement can be used to good advantage in collecting grasshoppers of all ages—from the youngest to the adults. There are many modifications in the construction of these hopperdozers, but the form here described and figured, the writer has had made for him, and he has employed it in the fields and knows from experience that its use is

Deciduous Fruit Culture

By J. W. MILLS

MOTH CATCHERS.

THERE is still a lingering suspicion among many apple growers, that the lantern in an oil filled basin, is a feasible way to catch the codling moth.

This is a question that has been settled by careful tests in all parts of the country for several years. There are, However, many growers who cling to the idea that the lantern trap is profitable to use. Any person who is interested and will visit the office of the Horticultural Commissioners, will see an exhibit of a collection of insects caught in a lantern trap. There are nearly 100 insects, mostly moths, only one of them being a codling moth.

The Cornell, New York Station issued a bulletin in 1902, in which are given the reasons why the trap is a failure. It says that most of the grasshoppers, many of the true bugs, like the squash bug, all the butterflies, many of the moths, the peach tree borer moth, many beetles and most of the flies are day fliers and are not attracted by a light. A lantern trap may easily catch ten or twenty thousand insects in a season, but most of the household pests and fruit and garden pests are not attracted. Only about ten per cent of the injurious kinds are the females and they have almost invariably laid their eggs. About as many friends as foes are among the beetles are caught.

A strict account kept in Canada showed that one-third of the insects caught in this way were beneficial. In New York the number of injurious and beneficial insects was about equal. It must be borne in mind that the injurious insects do not destroy any of the beneficial kinds but one of the latter will kill many of the injurious kind. It will be seen from this, that it is not the number that is caught, but the kinds that are caught.

The potato worm moth is attracted by light at night, but the light must be used at a certain period or it will be of little use.

The geographical distribution of insects has been brought out in an interesting manner by the experiments with lantern traps. At the Canada Station one lantern trap was run three months and caught 2000 insects. The New York Station ran one four months and caught 13,000 insects representing 350 species. A lantern trap in a Texas cotton field caught in one night nearly 13,000 insects. It would be interesting to know how many might be caught in Central America in one night.

SPRAYING FOR CODLING MOTH.

The knowledge that spraying with arsenic solutions will reduce the injury done by codling moths greatly, is of little use unless the life history of the moth and worm is known. It commences in the spring from the larva or worm which has lain in the cocoon all winter. This worm pupates or goes into the chrysalis form when spring weather comes and in a few days comes out as a moth. It then flies about during the day time and lays its eggs on the apples just out of bloom and also on the leaves of the tree. The moth is active about four days; the eggs require about ten days to hatch and the worms live about 20 days before they spin their cocoons.

Now this will give an idea when to spray. As Prof. Melander of the Washington Station says: "The object of spraying is to coat the food of the worm with poison, so that its first meal will also be its last." He suggests that the best way to determine the time to spray, is to put a few cocoons in a Mason jar, with a cloth cover on it, and watch when the moths hatch out, about a week after this period spray. This will come about two weeks after the blossoms fall. By that time the blossom end of the apples closes in and the poison cannot be made to enter it. Moth eggs will be laid there and wormy apples will be the result unless the spraying is done just after the blossoms fall. In about two weeks the worms hatch and the spray material has lost some of its effiency through the expansion of the apple and the action of the elements. Consequently, the trees should be sprayed again at this time It is useless to spray from this time on till the next crop of worms appears. The time can easily be determined by placing some of the first found cocoons in the jar and watching them hatch. As soon as they first hatch, spray again and one week later spray again. A last spraying may be done in September if many wormy apples are found. Any sprayings between these specified periods is time and material wasted.

WALNUT GROWERS' INSTITUTE.

J. B. Neff, in charge of Southern California Institutes, announces an important meeting at Whittier on Wednesday and Thursday, June 5-6. It is called in the interest of walnut growers, and walnut growers from all over the State are expected. Prof. Wickson and Prof. Smith of the University and Judge Lieb of San Jose will be present and address the institute, as will many local growers.

The program is:

WEDNESDAY, JUNE 5.

10:00 a. m.—Introductory, Dr. J. A. Osmun.

Definite Methods of Fertilizing: Thomas Gooch, Rivera; R. McNees, Whittier; H. E. Collins, Rivera.

1.30 p. m.—

The Practical Value of Scientific Work in Prevention of Plant Diseases, as illustrated by Experiment Station Records: Prof. E. J. Wickson.

Important Facts to be Ascertained in the Investigation of the Walnut Industry: F. E. Kellogg, Goleta; C. C. Teague, Santa Paula; R. H. Sanborn, Santa Ana.

Irrigation and Cultivation of Walnuts: P. F. Coggswell, El Monte; B. F. Porter, Fullerton; C. G. Sanderson, Whittier.

7:30 p. m.—Question Box.

Pathological Laboratory: C. C. Chapman, Fullerton; E. G. Ware, Garden Grove.

The relation of the University to the Pathological Laboratory, and to the walnut grower: Prof. E. J. Wickson, Berkeley; Capt. G. L. Smith, Carpenteria.

THURSDAY, JUNE 6.

9:30 a. m.—Question Box.

The Possibilities of Improvement in Walnuts: Prof. E. J. Wickson, Berkeley; L. B. Hogue, Santa Paula.

Experiment work in Progress, and Proposed by the Pathological Laboratory: Prof. R. E. Smith, Whittier.

1:30 p. m.—Question Box.

The Walnut Industry: Judge S. F. Leib, San Jose.

AGRICULTURE IN OUR INDUSTRIES.

In an address delivered recently at Pittsburgh, Secretary James Wilson spoke of the growth of scientific farming in the semi-arid sections of the west, and, in the course of his address, declared, "the time is not far distant when the semi-arid sections of the west will feed the nation independent of irrigation." In the course of his lengthy address replete with interesting matter the Secretary spoke of the results achieved in desert farming as follows: "After years of laborious exploration by government scientists, the methods of the people in Africa and Asia, who have learned to farm where the rainfall is light, have been adapted to the dry regions of the American continent from Texas to the Dakotas. Wheat imported six years ago yielded over 50,000,000 bushels last year, and this increase will grow in magnitude of yield, and spread of area, until the semi-arid country west of the ninety-ninth meridan will eventually produce most of the bread of the United States independent of irrigation."

Again, referring to the class of men engaged in agriculture at the present time, Mr. Wilson said:

"The most successful farming in our day is carried on by men of highest intelligence regarding all that pertains to the soil, the plant, the animal and the market. The American producer from the field would not be the potent factor he is without the inventor to perfect his machinery and the carrier who transports long distances at low rates; nor would he play the part he does in the world's markets with poorer soils and less genial climates.

"A vigorous movement by Federal and State agencies is in progress to educate the young people of the farm and to make research into the wide field of science that pertains to producing the nation's food, clothing and other necessities. Discussion has been active for a generation or more regarding the preparation of the farmer for his life work. Many educators think the farmer needs nothing beyond a common school education. Many legislators think that money devoted to training farm people is wasted. The Federal government has voted lands and money to educate the children of the farmer and the mechanic has endowed institutions to make research. The States have followed the lead of the Congress, and something is being done in each of them, much is being done in some of them to teach the sciences of agriculture. The movement among those interested is so strong that the old-fashioned educator and the hostile legislator are getting into the minority.

"As agriculture develops and becomes systematized the relations between the farmer and the man in the city will become more intimate. Thousands of tons of produce are grown which must be handled quickly, sent into our city markets, and disposed of. Thus have developed the great problems connected with transportation, storage, and the general handling of perishable products, such as fruits, vegetables, etc.

"On the Pacific Coast 30,000 carloads of oranges are produced every year, and most of these must be sent across the continent to be distributed in our eastern markets. Hundreds and thousands of carloads of these fruits are destroyed through improper handling, and hundreds and thousands of carloads of other perishable fruits, such as peaches and apples, are similarly lost through bad methods of handling.

"The department is studying these questions and pointing out to the grower how he may so improve his methods as to prevent his losses; pointing out to the packer how he may handle the fruit and perishable products so as to help the grower; and pointing out to the transportation companies how they may conduct their business to the end of placing the goods in the hands of the consumer in good condition.

"Besides this, the department is pushing investigations with the view of placing these choice fruits across the water in the markets of our European neighbors. Special methods must be devised for handling and shipping these long distances. We have shown how peaches may be shipped and placed on the Liverpool and London markets as fresh as when they were taken from the trees. Such fruits have yielded handsome profits and open the way for the clearing of our markets in times of overproduction."

TO MAKE KEROSENE EMULSION.

Dissolve a half pound of hard soap in a gallon of hot water and then, away from fire, add two gallons of kerosene. Churn the mixture briskly for five minutes or more until the whole mass has a uniform creamy consistency. This may be readily done with a bucket pump by taking the noozle from the hose and pumping the stream back into the mixture. Then dilute with fifteen to twenty gallons of water.

The above has been given often in the Cultivator and is still called for by many subscribers. Cut it out and paste in your scrapbook.

Above all things, plan your work. "Foresight is better than hindsight" in farming as much as in anything else. Have the hired men understand what they are to do to-morrow as well as to-day. A careful planner is generally, to use a back East expression, "forehanded."

If it can possibly be managed, don't borrow other people's implements. Sometimes, however, this is unavoidable, and in such a case return the borrowed articles promptly, and in as good or better condition than when received—then it will be an easy thing to get it again when needed.

Try and establish a farmer's club or a Grange in your neighborhood. Invite the neighbors to meet and discuss subjects of mutual interest. It will be suprising the benefits derived from these neighborhood meetings.

How much more attractive fruit looks when placed on sale if a few fresh leaves are placed among it. We are of course alluding to local trade.

"Do let me have the lounge, my son; my discourse was unusually long, and I am very tired."

"But, dad, I listened to it."

The Little Red School House

IS FOUND in the rich farming country of Alberta, Canada, just the same as it is found on the prairies of the central or eastern states.

In fact, facilities for educating your children are just as good in Alberta as they are in any section of the United States.

Western Canada is keeping abreast of the times, and in the matter of making money from agricultural pursuits it is ahead of any other country on earth.

Live stock and crops can be produced cheaper there, and in larger quantities, than in any other part of the world.

The rich grasses to be found on the plains of Southern Alberta produce better and fatter live stock than any other grasses known, and with the addition of a little water almost any kind of grain or vegetable can be raised.

In order to suppy the necessary moisture a large irrigation project is now under way which will supply water to the very richest portion of this great Canadian province.

The Canadian Pacific Railway Co. is building a vast system of ditches, which, when completed, will water about 1,500,000 acres of this rich land.

Land under this system of ditches is being offered at prices so low any man with a small amount of money can find a home there with the assurance that with one or two crops the land will be paid for.

On the vast irrigated tracts of Southern Alberta you can find a farm that will just suit you, and you can rest assured that if you farm it fifty years you will never have a crop failure.

Full information and particulars how to see the land, terms of sale and prices will be sent upon application to

Canadian Pacific Irrigation Colonization Company, Limited,

Sugar Beet Pulp
(Kow-Sauer-Kraut) For Cows

Q. What is a cow?
Ans. She is a square critter, with a peg at each corner to stand on.

The Cow Talks: I have also been called a "milk-machine." To a nail-machine they feed wire and get nails. So they expect to feed me wire-y, dusty, musty hay and get milk. Nothing in it. Don't expect to get wire nails from a nail-machine without feeding it wire, nor milk from this milk-machine when fed on wire-y hay mostly trodden under my feet.

I'll tell you what to feed me—give me Kow-Sauer-Kraut when I come in from the pasture.

Kow-Mathematics: Then I'll give you 32c worth of milk for a cent's worth of pulp. Besides, I figure I'll get fat at the rate of about a pound a day. (MRS.) A. LEAN COW.

P. S. You can get cured Kow-Sauer-Kraut at $1.00 per ton from the silo of the

Los Alamitos Sugar Co., Los Alamitos, Cal.

The Cream of Cream Separators

The Sharples Dairy Tubular is the cream of cream separators—the pick of the whole bunch. Supply can waist low, you can fill it with one hand. All gears enclosed, dirt free, absolutely self-oiling—no oil holes, no bother—needs only a spoonful of oil once or twice a week—uses same oil over and over. Has twice the skimming force of any other separator—skims twice as clean. Holds world's record for clean skimming.

Bowl so simple you can wash it in 3 minutes—much lighter than others—easier handled. Bowl hung from a single frictionless ball bearing—runs so light you can sit while turning. Only one Tubular—the Sharples. It's modern. Others are old style. Every exclusive Tubular feature an advantage to you and fully patented. Every Tubular thoroughly tested in factory and sold under unlimited guaranty. Write immediately for catalog J-260 and ask for free copy of our valuable book, "Business Dairying."

By Mrs. Minna E. Sherman, Fresno, Cal.

CONDIMENT FOODS AND CONDITION POWDERS.

MANY of the sicknesses that trouble horses and cows are those produced by unnatural conditions of life. They are heavily fed and when they take cold, inflamation starts at once, the animal stops eating for a few days to rest the stomach, for this is Nature's way of curing these troubles. The tendency of the owner is to rush to condition powders or condimental foods. The most of people do the same thing with their own stomachs, they at once begin to have special dishes cooked or take to whiskey whenever the stomach rebels against its overload. A little resting does great good; even if the trouble is serious, it is better to have the stomach free from a mass of undigested food.

Evil Effects.

The results sometimes obtained from feeding condiment foods are undesirable because used wrongly. We feed alfalfa with water for breakfast, then water and alfalfa for dinner, then alfalfa and water for supper, until the cows sigh wearily over the task of converting the same things day after day into milk. Give them a little of one of the condiment feeds and see how they will enjoy it. Try them also with a little common mill stuff, and see how they will enjoy that. Then count the difference in the cost between the two and see how you will enjoy it! The complete change is to the cow was grateful as it would be to a person. Often a little sweetness added will help the cows. A handful of raisins or figs will be received with pleasure. Molasses is also enjoyed by all stock and if it is cheap enough, the horses and cows can have their grain moistened with a pint of it at each meal for a change. A pint has to be the limit at first or the animal may be purged. A horse can be quickly put into show condition by feeding barley boiled and sweetened with molasses.

Salt.

A cow in milking requires to balance up the excreta, nearly two ounces of salt a day, while a horse uses less than an ounce and a half. In the East this salt has to be supplied, so that all the condiment foods are heavily salted. Here in California there are herds of cows that never receive a bit of salt. The owners have found that the cows reject it, as there is salt enough in the ground for all their requirements. We always keep salt where the horses and cows can have it and let them help themselves. They eat but little of it. I do not believe it would be wise to force the salt on them, while it might not be injurious. It is certainly far from pleasant for any one of us to have to eat more salt than we like, and then have to drink an extra amount of water to carry it out of the system.

May be Advantageous.

After all is said against the use of condition foods and powders, a little condiment food can be used at times with advantage by every dairyman, yet he can mix it himself. The drugs used are aromatic seeds, with such vegetable tonics as gentain, Virginia snake root, cascarilla with salpetre and sulpher added, sometimes copperas is used. These are only used in small quantities, and the bulk of the feed is linseed meal, cotton seed meal, corn meal, shorts, bran or cheap flour in the good honest brands.

A Formula.

The following quantity will make one ton of excellent stock food. At the time it was made we were growing beans on the ranch:

Linseed meal 800 pounds, ground beans 925 pounds, Indian meal 433 pounds, powdered tumeric 30 pounds, powdered ginger 3 pounds @ .09, 27 cents; powdered Fenugreek, 2 pounds, @ .25, 50 cents; powdered Coriander seed, 2 pounds, @ .05, 10 cents; powdered Gentain, 10 pounds, @ .045, 45 cents; cream of tartar, 20 pounds, @ .30, $6.00; flour of sulphur, 10 pounds, @ .02, 20 cents; salt, 5 pounds, @ .01, 5 cents.

The total for drugs and aromatics $7.12. While the prices may be a little higher than when I purchased last year still they are not very far out. The recipe for this food is one of the best that is now on the market and sells for twenty-five cents a package or at the rate of $500.00 a ton.

Use in the Proper Way.

The ranch mixture is used in bringing up any thin cow to proper condition or flesh, when the cow is once in fair order stop the use of the drugs and put the cow on a little plain oil cake, for the digestion may be injured if unduly forced.

The old idea that the cows' stomachs were burnt out if they were fed any grain has a foundation in the fact that show cattle are over fed and dosed to hold them up under the fatigues of the show ring. These cows often go off condition badly and have to be turned on the grass until they recover.

The Formula for Bloating Cows.

Linseed meal 100 pounds, sugar 20 pounds, corn meal 200 pounds, ground gentain 2 pounds, sulphur 4 pounds, ginger 1 pound; caraway seed ½ pound, anise seed ½ pound, bicarbonate of soda 5 pounds. Use half a pound of this instead of the same amount of the regular ration, twice a day.

LIME WATER GOOD.

The question is often asked, "What is a good cleanser of dairy utensils?"

An excellent preparation will be found in lime water. This may be made by dissolving a pound of lime in water and when slacked add enough water to make six gallons. Let it stand until the lime particles settle and use the clear water on top to wash the utensils. This will be free from germs and bacteria of every kind and will be death to those with which it comes in contaca within the utensils.

Old sour swill barrels are not favorable to the health and well being of hogs and pigs. Old decayed milk is a germ breeder and is not fit for any creature as an article of food. It should be "cast out and trodden under foot of men," or rather into the dunghill. Scald the barrels once a week.

CALF CARE.

Allow the calf to suck for about two days after it has been dropped. It is not necessary that it be with the cow at all times, but it should be allowed to assist in removing all the cake from its mother's udder. Some object to allowing the calf to suck at all, but I have had the best success by allowing it to suck for at least forty-eight hours. Of course, the calf is harder to teach to drink after it has been allowed to run with the mother for a while, but, it is much safer for the cow, especially if she is a heavy milker. It is impossible for the dairyman to remove all the cake when the milking is done by hand and then the mother will have her mind upon her calf and will refuse to "give her milk down."

As soon as the udder is normal after calving, remove the calf and teach it to drink. While it should not be starved, it should be allowed to become very hungry that it will willingly eat, even if its eating is not exactly in the natural way. For the first week it should have whole milk. Then begin feeding whole milk in the morning and a mixture of equal parts of whole milk and sweet skim milk in the evening. Follow this for another week. Then make both evening and morning feeds equal parts of whole and sweet skim milk. At the end of another week make the evening ration entirely sweet skim milk and at the end of another week make the entire ration sweet skim milk. In this way the change is made so very gradual that the calf is not affected by it.

It should be taught to eat a little corn meal as early in its life as possible. Skim milk contains more protein than any other important food element and it needs a fat-forming food to take the place of the cream which has been removed. This can be supplied in corn. Give it at first in the form of partially cooked gruel, giving about a teacupful to each calf. At the end of two or three weeks, the gruel can be replaced with raw corn meal. After the calf has learned to eat it raw, it should not be mixed with the milk, but fed in a box or trough. As soon as possible get the little animal out upon the pasture.—S. E. Wallace.—In Journal of Agriculture.

CALF SCOURS.

The time is near at hand when young calves will be troubled with scours unless watched closely and fed carefully. Too frequent sucking will bring on dyspepsia and this leads to scours. Allow the calf to suck at regular intervals. In this way it will not take too great a mass into the stomach at any one time. Should a serious case of scours occur, the following remedy given by Dr. Snead will be found of value, often effecting a cure at once:

"Give a dose of castor oil to clean out the bowels, then follow with two tablespoonfuls of the following every six hours until the scouring stops: Tincture of opium, tincture of ginger, tincture of rhubarb and essence of peppermint, equal parts. Give this in a pint of lime-water. It is a good plan to give in addition to this a tablespoonful of dried blood in the soft feed."

Dr. Salmon, a good authority says: "Treatment should vary according to the nature and stage of the disease. The first thing is to remove the irritant matter from the bowels. For this give one to two ounces of castor oil. Then reduce the milk to one-half that formerly given. If the stools smell sour, the milk may be replaced by one ounce of calcined magnesia and in any case a tablespoonful of lime-water must be given at each meal. When the offending agents have been removed by the castor oil,give one dram of anise water, one dram of nitrate of bismuth and one dram of gum arabic, three times a day. Under such a course of treatment the stools should become natural in a day or two."

INFLUENCES BEFORE BREEDING.

But the influences during pregnancy are not the only ones which affect the offspring. There are certain things to take into consideration before breeding the animals. One of these is selection.

This brings us back to one of the laws of breeding which was considered in the first article, the law that like produces like. By selecting breeding stock which conforms to the ideal we are able to substitute new breeds and perfect those which have been instituted. Occasionally there is a variation and if we select two similiar specimens of a variation and use them as the breeding stock we are able to lay the foundation of a new breed. This is no doubt how the so-called owl pigeons came into existence. By variation the first specimen or two came into existence and by selecting them as breeding stock the foundation for a new and novel breed was laid. Then by selecting the offspring which were true to the new type and using them as breeding stock, the breed was perfected.

At this point the principle of in-and-in breeding can be employed to a great advantage. By in-and-in breeding is meant the breeding together of animals which are very closely related. It often becomes necessary to breed brothers and sisters together in order to perfect a certain type. In-and-in breeding is usually necessary in forming new breeds, and it is absolutely necessary in perfecting these breeds. When a brother and sister have desirable qualities and so far as the breeder knows no other animal on earth has the same qualities, it becomes necessary to breed these two close relatives together to perfect the type desired. When the breed is already established, as is the case with all the well-known breeds of horses, cattle, hogs and poultry, in-breeding is by no means necessary and the breeder practicing it is only inviting disaster. Where it is continued for a number of generations, or is practiced by the amateur, it invariably results in a type of animals which are little better than runts. They have a weakened constitution, and if the practice is carried too far the animals will lose the power of reproduction.

The only thing necessary for the breeder who is attempting to raise the established breeds, is to keep up the health of the herd and to breed to keep the animals true to the type. To maintain the health of the herd it is necessary to maintain the constitutional vigor. The constitutional vigor may be told by a broad, deep, compact form, with a barrel or coupling which is reasonably large, but neither too long or too short. The head should be short and wide between the ears. Much width between the ears means development of great nerve power. Nothing denotes the health and vigor of an animal more than the eyes. When the animal is healthy, the eyes are full and clear, but as soon as it is stricken with disease, the eyes become weak and lose their clearness. A wide breast and chest also show strong constitutional vigor. This means roominess and great vital force. The vital organs have much room for action, and when this is the case the animal will surely be healthy. The breeding animals should have a lively carriage. If the animal is vigorous, it will show the fact in its carriage. It will be spry and move about with no uncertain step. If it is ill or suffering with some constitutional disorder, it will move about slowly and its action generally will be so faltering that it can be easily told by even the inexperienced person.—Journal of Agriculture.

PIGS AND ALFALFA.

Pigs will show a much more rapid development if alfalfa is mixed with a little grain to balance the ration. Pigs will grow, of course, on alfalfa and make a rapid growth, but they will do better to mix a little grain daily with their feed. The grain is needed to increase the number of pounds of food elements without correspondingly increasing the amount of dry matter.

Several years ago the Nebraska station made an experiment to learn what proportion of grain to alfalfa was needed to make the most economical ration for growing hogs. It was found that the cost of producing 100 pounds of gain on alfalfa pasture alone, was about $4.30. On alfalfa pasture with an addition of one and one-third pounds of grain the cost of 100 pounds of gain was lowered to $2.74 per 100. When the grain ration was increased to two and a half pounds per day, the cost was lowered to $2.45. It can be seen by feeding only one and a third pounds of grain ration per day, the cost of producing the 100 pounds of gain was lowered nearly one-half. While one single test should not be taken as reliable, it certainly shows that pigs should not be expected to pass the summer without a little grain ration.

CURE OF FOUNDER.

The question is often asked, what is Founder in horses, and what will cure it? The books describe founder as being similar to acute rheumatism, or rheumatic fever, sometimes affecting the muscles of respiration and sometimes the heart itself. It is is known that if the overfed horse is even slightly exposed to exciting causes, founder will rapidly develop.

Dr. Dadd advises the use of the following nauseating cathartic: Powdered aloes, six drachms; pulverized lobelia, two drachms; warm water, one pint. After this has acted, give a dose of cream of tartar, sulphur and podophyllum, each two drachms in a pint of warm water as a drench.

These remedies should be given as soon as the trouble appears or they will be of no avail.

The stallion which does not mark his colts should not be bred to. The stallion is, or should be the better animal of the two and he should be so prepotent that he is able to impress his superior qualities on the colt. If he fails to do this, he is generally but a very little better than a scrub horse.

HOLSTEIN TRANSFERS.

From the Bulletin of the Holstein-Fresian Association, we learn of the following transfers of registered bulls in this State:

Ciruela Mechthildus, Dr. C. W. Evans to J. W. Davison, Modesto.

Damisela De Kol, Dr. C. W. Evans to C. M. Beckwith, Modesto.

Paul Butter Boy of Riverside, Chas. D. Pierce to F. F. Pellissien, Los Angeles.

This is the season of the year when special attention should be given the shoulders of horses. Keep the collars clean by washing and frequent oiling. Wash the necks in the evening after the day's work is done to remove sweat and dust.

BALANCED RATIONS.

During the winter of 1902-3 at the Nebraska Experiment Station the value of alfalfa hay when fed in connection with corn was carefully tested.

The experiment lasted during a period of 12 weeks. One lot of five shoats was fed corn meal alone, while another lot containing the same number of shoats of similar quality were fed 80 per cent. corn meal and 20 per cent. alfalfa.

At the close of the experiment it was found that the average gain per hog in the lot fed corn alone was 78.6 pounds, while the average gain per hog in the lot fed corn and alfalfa was 101.6 pounds, a difference of 20 pounds per hog in favor of the corn and alfalfa ration. In the lot fed corn alone each 100 pounds of gain cost $4.48, while in the lot fed corn and alfalfa each 100 pounds of gain cost $3.40, a decrease of $1.08, or a little over 24 per cent. in the cost of producing each 100 pounds of gain. The point which interests us is that this wonderful lessening of the cost of production was brought about simply by feeding a balanced ration, and one which nearly every farmer has at his command.

It is almost startling when we stop to think that if only one-twentieth of the corn produced in Nebraska during the past season is fed to hogs as a single food, according to the figures which we have just quoted, more than a million dollars would be added to the wealth of the state if alfalfa should be substituted for one-fifth of the corn, thereby making a balanced ration. It has been well said that corn is the king of hog feeds, but it may be as truly stated that alfalfa is queen. Where one is there should the other be also.

Another experiment which brings out the value of the balanced ration very plainly was conducted at the Iowa Station.

Twelve excellent cross-bred shoats, averaging 205 pounds each, were divided into two lots of six each. One lot was fed corn alone and the other lot was fed corn and Swift's digested tankage.

At the end of 49 days it was found that a ration of corn alone had produced 100 pounds of gain at a cost of $5.10 while a ration of corn and tankage had produced 100 pounds of gain at a cost of $4.50, a difference of 60 cents a hundredweight in favor of corn and tankage. The lot fed on corn alone returned 83 cents for each bushel of corn fed, while the lot fed on corn and tankage returned 97.5 cents for each bushel of corn fed The net profit per hog in the lot fed corn alone was $2.39, while the net profit per hog in the lot fed corn and tankage was $3.22, a difference of 83 cents per hog in favor of the corn and tankage ration.

The lesson taught by this experiment is plain. It shows that by simply adding tankage to corn, thereby making a balanced ration, the net profits per hog were increased a little over 34 per cent. It was after reading the bulletin containing the facts which we have just stated that we decided that, in the absence of alfalfa, it would pay to buy tankage or some other by-product rich in protein to feed in addition to corn to the hogs we were then feeding for market. A careful trial convinced us that the plan was a good one, and we have continued the practice from that day to this.

The balanced ration has another value which we have not yet mentioned. It is a value measured not in dollars and cents, but by the increased health, strength and vigor of the hogs to which it is fed. It is the value which should appeal most strongly to the pure-bred swine breeder.

As a result of feeding a balanced ration, there is not only a larger proportion of lean meat, but there is a greater development of the internal organs, and healthier, thriftier hogs are the result. There is hardly room for any doubt that if more attention was given to supplying our hogs with balanced rations there would be a decided improvement in their size, quality and vigor, and a consequent decrease in the losses from cholera and other diseases.

The feeding of a properly balanced ration also has a very beneficial effect upon the strength and density of the bones, as was revealed in a recent slaughter test at the Nebraska Experiment Station.

The strength of the thigh bones of a pig fed on corn and alfalfa were tested in a machine constructed for that purpose. It was found that the bones of the corn-fed pigs were one-sixteenth of an inch larger in diameter. The thigh bones of this pig broke under pressures of 320 and 339 pounds, while the bones of the corn and alfalfa fed pig broke under pressures of 500 and 520 pounds.

This test brought two important facts to light; first that the ability of a hog to stand well upon his feet is a matter of density of bone rather than size, and, second, that that density of bone may be secured by feeding a properly balanced ration.

Since one's profit may be increased 25 to 35 per cent. by feeding a balanced ration, and since such a ration adds greatly to the health and strength and vigor of the hogs to which it is fed increasing their ability to withstand the inroads of disease, and rendering them better able to perform the function of digestion, assimilation and reproduction, it would seem that no one would continue the old method of feeding corn alone.—R. H. Searle.

WHEN TO BREED SOWS.

A subscriber asks: "How soon can I breed my sow for a fall litter after she farrows this month? If the sow has farrowed in May she should not be bred for six weeks, as to breed within that time time will bring the farrow in the hottest part of the summer, which is not good either for the sow or the pigs.

Inquiring boy to his mother: Ma, what did the moths eat before Adam and Eve wore clothes?

The Vegetable Garden

By ERNEST BRAUNTON

COMPARATIVE VALUES OF MANURES.

In a statement issued by Prof. Wickson some time ago regarding comparative values of manures, he said:

The excrement of different animals serve somewhat different purposes in garden practice because they act more or less quickly and are more or less stimulating to the plant. There is also warrant in carrying with the word "stimulating" the inference that in feeding plants, as in treating animals, that which is the most stimulating must be used with the greatest caution. Both caution and economy prescribe that the manure which has the highest content in plant food should be used in less amount and more carefully distributed through the area of the soil which the roots of the plant are expected to traverse. The excrements of animals depend in composition upon the abundance and richness of the food furnished them. The following table is compiled from experiments and analyses made at the Cornell University, and there is no doubt that he stock was well fed:

Animals	Nitr. P. C.	Pot. P. C.	Phos.ac. P. C.	Val. P. ton
Cows	0.50	0.29	0.45	$2.37
Horses	0.47	0.94	0.39	2.79
Sheep	1.00	1.21	0.08	4.19
Swine	0.83	0.61	0.04	3.18
Hens	1.10	0.29	0.47	4.22

Value per ton is also conditioned upon the percentage of water in the manure. Hen manure has much less water even in the fresh state than that of cattle, and air-dried hen manure, free from earth, is sometimes worth as much as $10 per ton, providing the hens are well fed. California sheep manure has much greater value than that of Eastern corrals, the analysis showing as high as 2.32 nitrogen, 2.90 potash and 2.88 phosphoric acid.

IMPROVING THE QUALITY OF "RIVER" POTATOES.

There is a well marked difference in the quality of potatoes grown in the Salinas valley in California and those grown on the numerous islands of the Sacramento and San Joaquin rivers. This difference lies primarily in the greater "mealiness" of those grown in the region of Salinas. The difference is so great as to materially influence the price of the river potatoes unfavorably.

The yield obtained upon the island soils is extremely favorable and could the growers produce as high a quality and obtain as high a price for them as do the Salinas growers, there would be a material gain in their income.

Physically, the soil of the island sections is unusually well adapted to the production of potatoes and root crops of all kinds, but in the matter of quality growers of the region have never been able to compete successfully with those whose lands are not as abundantly supplied with nitrogen in the form of decaying organic matter.

The abundance of this material gives to the tubers and roots an unusually large size but also tends to produce a more or less watery product. The writer is of the opinion that this may be the result of an unbalanced ration—too much nitrogenous matter in proportion to the mineral plant food available for the crop. Could the condition be remedied, it is believed that there would be a marked improvement in the crop. Should this be found true then there is no crop upon which it should pay better to feed with the mineral plant foods, potash and phosphoric acid.

At the present time there is little fertilizer of any kind used on the large potato plantations of the islands, but growers are recommended to make a thorough trial of these materials, not so much with the idea of increased yield, but more particularly with respect to an improvement of quality of the product.

Stable manure is not a proper source from which to obtain plant food for this crop, for it has been shown that it is almost certain to make the tubers scabby, irregular in shape, and will still further affect the texture. There is already too much nitrogen in these soils and any further addition in the shape of stable manure would but increase the difficulties already existing. A crop of 200 bushels of potatoes removes from the soil in tubers, etc., 46 pounds of nitrogen, 74 pounds of potash, and 21 pounds of phosphoric acid, which clearly shows the needs of this crop for mineral plant foods. These soils furnish to the crop an abundance of nitrogen, but are short in the mineral matters, potash and phosphoric acid. These should be supplied.

The requisite material can be added by the use of 1000 to 1500 pounds of a fertilizing material containing actual potash 9 per cent. and available phosphoric acid 6 per cent. Even larger quantities than this have been used. Potatoes, like all starch producing crops are large users of potash and need liberal supplies of this element. Experiments made at the New Hampshire Station showed that potash was the most important element for this crop.

Numerous experiments have also shown that of the several forms in which potash can be obtained on the market, the sulphate is the most desirable for this crop. The phosphoric acid may be obtained in the form of either bone or rock superphosphate, or Thomas slag. If the latter is used it is absolutely necessary to work it deeply into the soil. In fact, it should be plowed into the land. Harrowing will not suffice to place it deeply enough in the soil.. The following has been found a very satisfactory manner of applying the fertilizer for this crop.

The land is first marked and a furrower is run along the rows, making a furrow about four inches deep. In this furrow the fertilizer is applied either by hand or with a distributor, and well mixed with the soil. The mixing is best done by running a cultivator along the row, for if the distributor is used, a mixing attachment can be used thus doing the distributing and the mixing at one and the same operation. The potatoes are then dropped in the furrow and covered. If it is desired to cultivate both ways the land can be marked across the furrows after the fertilizer is applied.—Geo. Wright.

Loveliest of lovely things are they
On earth that soonest pass away—
The rose that lives its little hour
Is prized beyond the sculptured flower.
—Bryant.

CONGO ROOFING

NEVER LEAKS

Congo is the "Never-Leak Roofing."
Looks like rubber—but never hardens and never cracks.
Defies water, acid, sun and fumes.
Fire-resisting, durable, low in price, light in weight, high in quality.
Comes in rolls ready-to-lay—any one can do the work. No special tools required.

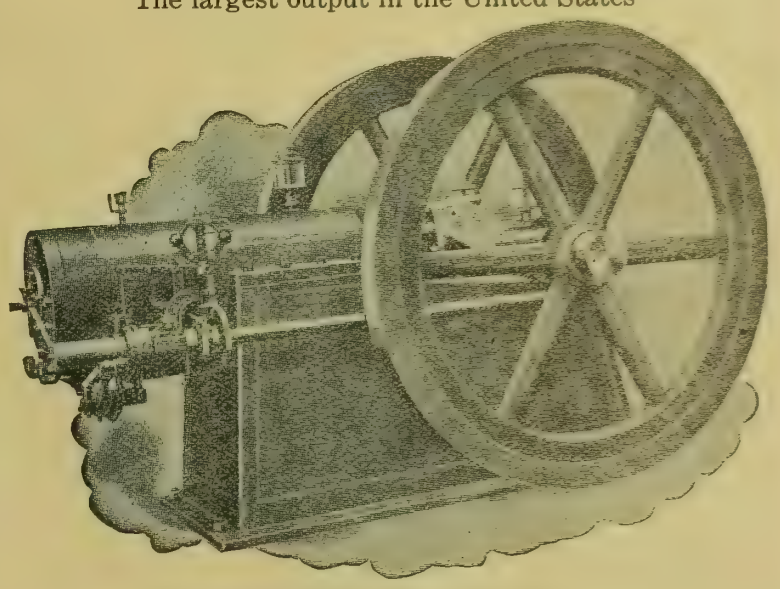
Columbus Machine Co., Columbus, Ohio

Have stood the test sixteen years.
The largest output in the United States



Standard Horizontal, 4 to 60 H. P.

Read what this man says about Columbus Engines:

Greenleaf-Compton Company, Tropico, Cal., 4-3-07.
121 So. Los Angeles St., Los Angeles, Cal.

Gentlemen—For about four years, I have used a Columbus engine of ten (10) horse power; which has been running a 3½ Vertical pump and pumping about 35 inches water with a 90 foot lift, and when the time came to buy a new pumping plant for my ranch near Anaheim where we we shall need water for about 200 acres, I decided to have a 60-horse Columbus engine installed, and placed the order with you because I expect to have a pumping plant that cannot be excelled.

Respectfully, E. B. BARY.

This 10-horse engine is pulling 13½ horse power. We are installing a 60-horse plant for Mr. Bary, 3½ miles north of Anaheim. Come in and let us demonstrate the simplicity of Columbus Engines.

Greenleaf-Compton Co.

New System of Irrigation Flumes

Made of 2-inch iron tubing with holes any desired distance apart. Easy to lay, requires no repairing.

Cheaper Than Wood Flumes

Will last for years. Can furnish in any quantity. We also carry in stock several thousand feet of all sizes of standard pipe, and a general line of second-hand machinery. Engines, Pumps, Hoists, Pulleys, and Belting of all kinds.

R. Kelly Machinery Co., Cor. Mission Road and Macy St., Los Angeles, Cal.

When writing advertisers, mention Cultivator.

Does this stream of water look good to you?
It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.
It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.
How many pump users can say this?
It shows conclusively that it pays to install good machinery.
We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

California Horticulturally

By JOHN ISAAC, Sacramento, California

GOOD OUTLOOK FOR FRUIT.

LATER reports are to the effect this season will be a good one, that the fruit crop as a whole perhaps somewhat short of normal, but very much better than that of last season. There is an assurance of a good demand and consequent good prices which promise to make it the most prosperous season that the grower has had in many years, even if there is a light shortage. Reports from different sections vary greatly and rather indicate that the crop will be spotted. Peaches in some sections are given at not over one-third of a crop, in others they are reported as full and very heavy. In spite of early predictions, however, it is safe to state the fruit crop of the state as a whole will be at least fair and prices very good.

CANNERIES ACTIVE.

The canneries of Northern California are already being put in shape for the season's campaign and it is announced that they will put up the largest pack of fruit in their history. The stock of canned goods on hand is nearly exhausted and the demand for new goods is active. Very large orders have already been received and it is doubtful whether the canners will be able to fill their orders. Several of the largest canneries have largely increased their capacity and the outlook is for a very busy canning season.

LITTLE PEACH BLIGHT THIS SEASON.

As was to be expected, there is little peach blight reported this season from those sections which were badly affected last year. Very many orchardists took no chances but sprayed with the Bordeaux mixture early in the season, but even those who have done no spraying, report the blight as decreasing. The fact is, that the peach blight is a fungous disease and is very largely dependent upon climatic conditions for its virulence. In some seasons, when conditions are favorable for its growth, it becomes alarmingly destructive, but will almost disappear another season. This disease has been known almost ever since we began to grow peaches in California, but has been rarely destructive for two seasons in succession. It is of an entirely different nature to the pear blight, but the destructive ravages of the later caused peach growers to become panic-stricken when the peach blight made its appearance. It is well to take every precaution against it, but there is no need to fear that this disease will ever be to the peach what the pear blight is to the pear.

PROSPECTIVE SHORTAGE OF LABOR.

The fruit growers of Sutter county some time since met and formulated a scale of prices which they would pay for the Japanese labor and agreed among themselves not to pay more. It is not improbable before the end of the season, that instead of sticking to their agreement, they will be breaking their necks to hire the Japs at their own figures. Supply and demand regulate labor prices as all else, and this season there is likely to be an active demand for any kind of labor and the grower who can get it at any price will be among the fortunate ones. The exclusion of the Chinese has cut off a very important branch of field labor, the great demand for labor of any and all kinds in the city at wages that the farmer cannot afford to pay is draining the country of its white laborers, the embargo now being put on the Japanese is already cutting that supply short. Eastern labor has all it can attend to at home and will not come West, and so it is directly up to the California fruit grower and farmer to look out for his interests in the best way he can. He may have to set his wife and children at work in the field, as in Europe, at which the average American mind revolts, but when crops are grown they must be cared for and that, with any labor available.

THE STATE FAIR.

Secretary J. A. Filcher, of the State Agricultural Society, is already moving in the matter of the next State fair, and it is his intention to make it the most successful one ever held in California. When Mr. Filcher took hold of the work last year, the State fair had fallen into disrepute. It had become a mere horse show and a racing and gambling event. It was roundly denounced by the press of the State and the best people took little stock in it. It was in this condition that Mr. Filcher found it, and it was a Herculean task to lift it out of the slough into which it had fallen but he went bravely at he task and the last fair was the first in many years that could justly be called a State agricultural fair. Many of the counties, however, from their past experience with it, refused to come in but there was nevertheless a good showing from various sections, and Southern California was represented by San Diego and Los Angeles. It is to be hoped that this season will see it a truly representative exposition of the whole State, and this it should be now, of all times, as it has been so arranged that it will be held at the time that the Irrigation Congress will be in session at Sacramento, and it is desirable that people attending this Congress should be enabled to see what the leading irrigating State of the Union can do in the line of agriculture.

VALUE OF GOOD ROADS.

The Department of Agriculture issued a bulletin showing the cost of hauling the principal crops to the nearest shipping point. Nearly $29,000,000 was spent in a single year to get the corn crop shipped, this item representing nearly 10 per cent. of the value of the average load carried. In the case of wheat the aggregate cost was nearly $22,000,000, or a little over 7 per cent. of the value of the load. Taking twelve of the principal products the aggregate cost of hauling to a place of shipment was $73,000,000. No better argument could be made in favor of good roads than this table of figures. The statistics indicate also the possible saving through the development of freight-carrying trolley lines, bringing the farmer nearer to the point of shipment. With an annual outlay of $73,000,000 for hauling $1,500,000,000 worth of ordinary products, it is plain that the savings secured by improvement of transportation facilities would be enormous.—American Farmer.

With the Citrus Growers

By J. W. MILLS

VICIA SATIVA.

DURING the past year we have had numerous inquiries as to the proper name of the vetch that is so extensively grown in Southern California.

We have been growing a number of legumes as green crops for a few years, and the best one so far tried is similar to that so entensively grown in the South. It differs but sligtly, in appearance being very smooth in stem and leaf but is fully three weeks earlier in maturing than is the kind most extensively used. That which was planted late in December has made its growth and matured seed, while earlier plantings of the other are just blooming. The growth of both is about the same. Samples of each were sent to Berkeley for identifying and we have just received a letter from Prof. H. M. Hall that both are Vicia sativa, one early and one late maturing variety. The early sort is less hairy than the late kind.

CUT WORMS.

Orange growers are in trouble in various sections on account of cut worms climbing the trees and eating both ripe and young oranges. This is due to the growth of weeds and green crops that have grown under the trees. We have heard some growers say that it cures them of growing green crops. This is rash talk for it it entirely easy to grow the crops and not be injured by the worms. If the weeds and green stuff are plowed under before worm time comes around, they will be destroyed in the main body of the orchard and by mowing the weeds from under the trees early in the season, the millers and butterflies will not have the proper kind of material on which to lay their eggs, and as a consequence they will keep away from there, confining their laying operations to those plants which may be turned under with a plow. This plan necessitates working systemmatically which is the proper way after all. However, growers who have large orchards cannot always keep up to date with all these jobs and keep in practice they "get caught" as the saying is with certain things undone that should be done. As a precautionary measure to be put into practice keep the lower branches trimmed so that they just clear the ground. One of the best growers in the State always keeps his trees trimmed so that the lower branches are ten inches or a foot from the ground. He claims that fruit that touches the ground is of little or no value anyway.

If trees are trimmed thus and no weeds extend up into the branches, the worm must ascend the tree trunks to get at the fruit. This being the case, they can be easily kept off by bands of fly paper or alfalfa poisoned with arsenic.

The latter is perhaps the quickest and cheapest. Boil one pound of white arsenic in two gallons of water with four pounds of sal soda till all the arsenic is dissolved. One quart in 40 gallons of water will make a strong poison of it, but a stronger solution will do no damage as long as none of it touches the tree or foliage. Dip freshly cut alfalfa in this and throw a handfull of it under each tree. By stirring in a few drops of oil or rhodium before wetting the alfalfa, it will attract the worms and a few bites of the poison stuff will kill them.

There are several ways of successfully combating the worms without resorting to clean culture. Orange growers especially cannot afford to abandon this practice of growing these crops as they are the life of the soil. Keep the lower branches off of the ground and there will be many advantages. A low constructed cultivator can then be run under the branches without injury to the trees and save much unnecessary labor. Home made implements of this sort have been made and operated with perfect ease. It is not advisable to trim the trees so that the lower branches will clear the ground more than a foot. This will give ample protection to the base of the tree and will not make the grove have the appearance of one that is high pruned.

The poisoned alfalfa is a good remedy for worms that attack grape vines.

FROM A FLORIDA STANDPOINT.

A writer in the Florida Agriculturalist in advocating plucking by hand instead of stem cutting of oranges gives a view of conditions in marketing and quality of fruit which may have some interest for California readers. We give extracts from it for what it is worth:—

"If the stem left on the orange by clipping strikes another orange with a fall of two feet it bruises or makes a hole, and if inoculated with the rot germs in the packing house it is very apt to inoculate the fruit it strikes.

How easy it would be, while experimenting, to drop those same oranges two feet or twenty feet, if onto soft plowed ground, and box or barrel them before they enter the packing house, and then compare the percentage of loss with those that passed through the packing-house. No need to ship them. Just let them stand a month where they can be watched and given the same treatment.

And why not try some broken or twisted off (not pulled, for that would plug the orange), taking the fruit in hand and turning it backward until the stem cracks, and then a slight twist brings it off, leaving the calyx still on the fruit, but no sharp stem to drop on and puncture other fruit. Then pack some in packing house and some outside, and note the difference, if any, between plucking and clipping. We already have the government report stating a loss of 15 percent from clipping, which added to the 70 per cent. caused by dropping two feet in a packing house, leaves very little sound fruit for the commission man to handle.

Why did those Australians abandon clipping after such a short trial? Are they fools and don't know a good thing when they see it? Or is it necessary to lose 15 per cent. by using clippers when they can be plucked easier and faster by using both hands at the same time?

Now, I am still shipping and will quote from a letter received from Newbern, N. C., dated March 2, 1907.

"I think all oranges have gotten here that have been started, but it took a long time. Some shipped January 24th getting here February 18th, and of course the worse for their long outing. You had better drop freight, for those longest out are in bad hard shape. (Notice no complaint of rot but of hardness.) It is wonderful how long they will remain good. Those shipped January 24th went to Charleston, and goodness knows where else, out twenty-four days (in sugar barrels), and yet in condition for sale, but when enroute so long they lose their gloss and fresh look, and take on instead a dull, wilted appearance. (They were wilted from drought before starting.) At this stage it takes talk to make sales, and generally a sample cut open to prove the deceptive appearance of the fruit, but where there is juice and that sweet it usually ends in a sale.

"At this season there is more loss in every way, and it is luck to escape to any considerable extent. The fruit being ripe does not stand long transit and rough handling so well and decay is the result. A barrel of ripe oranges from Florida here has a decidedly tough experience. Did you ever think of it? Started off in fine shape, and with a temperature of 60 degrees perhaps, they soon encounter a cold blast that makes them lumps of ice. The temperature then moderates, and the oranges warm up and sweat till the barrel shows the dampness in every crack, and in that condition they encounter freezing weather again, and finally arrive at destination either hard and firm from cold or undergoing their second sweat. It is wonderful how they stand it at all. And it does them no good, for it kills the nice varnish gloss, hardens and toughens the skin and deadens the flow of juice so that the orange is unfit for suking, which is a favorite way for many. All the fruit received since January 1st has pulled through just these conditions. Many of the shipments had to stand two freezes, in which the temperature fell to 16 degrees, and it would feel like opening the door of an ice house when the head of a barrel was taken off, and yet I have lost nothing during the season from cold, rapid sales carrying everything away before having a chance to dry up or rot. (How does that compare with 70 per cent. of rot in three weeks?)

"So far this season the California navel cuts no figure except, with the huckster, who wants something nice, bright and showy for his stand.

You will notice from the preceding that the rot cuts no figure, and the only complaint caused by the long time enroute is of the hard, stale look of the fruit after four weeks of abuse by weather and railroad hands. And yet when I packed those oranges they were so soft from the drought (and many of them "drops") that they would not hold their own shape, and I feared to pack a whole barrel with oranges alone and so filled the lower half with grape fruit and filled up with oranges. But instead of getting softer and rotting they got harder and looked so unsalable that I advised soaking them in water after their arrival. The culls in my packing house dried up the same way."

Oranges
and
Lemons
When the right varieties are properly grown and planted, are money makers. Our new booklet on Citrus Culture tells all about the standard sorts, planting, cultivation, irrigation and packing the crop. Over 100 illustrations and something like 50,000 words of text. The price is merely nominal, namely, 25 cents. May we have your name for a copy?

THE PRODUCE MARKETS.—Los Angeles Market; San Francisco Market. New York Citrus Market; California Citrus Shipments, 558-559.

LOCAL CIVIC PRIDE.

Taken as a whole California is a beautiful State. Scarce a locality anywhere that does not abound in lovely environments. Especially is this true of the section known as Northern California. There the typography of the country is inviting to the eye because of its varied scenery. Green-clad hills, rugged mountains, streams of pure water, and quiet valleys enchant the eye and attract the tourist as a home-maker. One thing, however, is noticeable in most of the small towns in the State, and even in many larger ones, for that matter; there is not enough attention paid to outward appearance. Streets are not kept clean; weeds are not cut and burned from the vacant lots; and there are too slovenly and unkempt conditions generally prevailing. It is some effort to clean up a town, and it also requires time and money to keep a place neat, but it pays to do it. The size of the town is not what makes it a desirable place to live in. A live, prosperous town is a desirable one, and such a town may be a small one. Every citizen should take a personal interest in its welfare. Each citizen is a part of the town and either helps to make or unmake the place. Prosperous citizens are always public spirited and united. They take pride in their community. They stand together and work together for the interests of the town. They don't grumble and spend their time phophesying failures of private undertakings, but always stand ready to do their part and to help make enterprise a success, and that is what makes a town worth living in.

Civic pride, pride in everything which pertains to the place in which we live is absolutely essential to the prosperity of all citizens. If this element is lacking, the town remains dead and the people become dissatisfied, the more progressive leave, and only the "let well enough alone" class remain.

California is wealthy enough now, to begin to devote time and money to civic improvements. We need a campaign of education all over the State. In the northern third, nature has done a marvelous work of its own, but it needs the genius of man applied to its conditions to acquire the rounding out of its possibilities. The mountain roads need work to make them what they should be. The streams need better bridges, the streets and roads need cleaning and hundreds of thousands of trees set out on their sides to beautify them and afford friendly shade from the boiling summer sun.

Nowhere are better natural advantages offered to make the "Switzerland of America" than in the naturally beautiful section of which we speak. No other part of California is so lovely in summer and if its people will organize local civic societies in every community, even if not a hundred souls reside therein, and these civic societies will address themselves studiously to the one idea of making all possible out the natural advantages they possess, how incredibly rapid would the changed conditions appear. No other section of the State would come anywhere near accomplishing such results in so brief a period of time. Water the one thing needed to develop conditions to their best, flows abundantly much of the time, and is easily obtainable when not flowing, where provided for in suitable reservoirs.

So the things essential to California's splendor, as a State, is enterprise, civic pride, and everlasting hustle on the part of its citizens. As a matter of fact, property values depend on the enterprise of the people.

NEW METHOD OF INFORMATION.

The country at large is interested in the plan being worked out by Representative R. P. Hobson, who has been elected a member of the National Congress from Alabama. Captain Hobson is putting into effect a novel plan of distributing agricultural information among the farmers of his district.

With the idea of securing for his people the best information on agricultural methods, he has secured a number of experts from the various bureaus of the Agricultural Department, and will personally go with them through his district. He has arranged a number of meetings and is making every effort to obtain a large attendance at each one. At these meetings he will speak, and he will also be accompanied by scientific lecturers from the Department of Agriculture who will give specific information on all subjects relating to crops grown in Alabama. It has occured to us that this novel method of promulgating scientific information, could well be adopted by members of Congress in nearly all sections of the country. They need not, necessarily, call upon the department at Washington for all their lecturers, but take well educated agricultural speakers from the various states, who are advised on agricultural subjects pertaining to their localities.

We are in an age of agricultural development such as the world has never before witnessed, and the necessity for advanced information is more apparent with every succeeding year. It seems to us that a campaign on the part of Congressmen along the line adopted by Captain Hobson, would do more to make them solid with their constituents, and insure their return to Congress in a far more substantial way, than by the old method of haranguing the people on political topics. We have adready had too much politics. We need more scientific education; we need enlightened speakers and writers of pronounced ability and experience to educate us along lines heretofore untraveled in the agricultural field. Captain Hobson is to be congratulated on the innovation he is making, and it is to be hoped his example may be followed by Congressmen in all the States of the Union, so that diversified farming may receive an impetus which it so much demands.

WALNUT INSTITUTE.

The walnut growers of the State will be interested in the announcement which appears on page 540 of the Cultivator, of a Walnut Institute to be held at Whittier, June 5-6. This meeting will be addressed by J. B. Neff, the veteran walnut grower, Prof. Wickson, Prof. Smith and Judge Leib of San Jose, as special speakers. One of the topics which will receive special attention will be walnut blight. Every grower in the State should be at this meeting.

The people of Utah have decided to segregate their Agricultural college from the State university. It is thought that by so doing a greater interest may be secured in the agricultural college.

GRASSHOPPERS.

Continued from First Page

both practicable and efficient. It is constructed of sheet iron, preferably galvanized, of reasonable thickness to insure strength, and, except for the end pieces, made of a single sheet 10 or 12 feet long and 26 inches in width. The front is formed by turning up one edge a couple of inches, and the back may be turned up a foot, thus making a shallow pan 1 foot wide, with the back the same height and with a front two inches high. Ends are riveted in and soldered, as shown in figure eight. Runners of old wagon tire are placed at each end (a, b), and another in the center (e) is turned over in the front and back to strengthen the pan at these points. These runners are riveted to the pan, as shown, and should extend both backward and forward in order to overcome to some extent the inequalities of the ground and cause the hopperdozzer to run more smoothly. By soldering it about the heads of the rivets the pan will be made water-tight. The pan is filled with water on which is poured enough kerosene to cover it with a film, a horse is hitched to the end runners, and the outfit is then ready for use. As the hopperdozzer is drawn over the ground the locusts will either jump into the kerosene and water direct or against the back and drop into it and there be killed. By using longer, wider, and heavier sheet iron a larger and stronger pan can be made and this further strengthened by additional runners; a horse can then be hitched to each end, or the pan may be mounted on low wheels. The whole thing is easily constructed, inexpensive, and once made may be put into service year after year as needed. The only place where its use will prove more or less impracticable will be on hilly or rocky lands.

Poisoned Baits.

Here again we have an inexpensive, practical way of dealing with these grasshoppers even when, as is frequently the case, they breed in the alfalfa fields and the protection, whatever it may be, must be applied there. What has come to be known as the "Criddle mixture" is giving most satisfactory results on the ranches of both the United States and Canada. The mixture is composed of half a barrel of fresh horse droppings in which is mixed one pound each of salt and Paris green. If the horse droppings are not fresh the salt is dissolved in water and mixed with the manure and poison. When this mixture is scattered freely about where the grasshoppers are abundant they seem to be attracted to it, for they devour it readily and are poisoned thereby. Dr. James Fletcher, entomologist for the Dominion of Canada, cites an instance where this mixture had been scattered freely around the edges of a field and states that his particular field stood out as a green patch in a brown plain, as it was situated in the midst of fields where nothing had been done to destroy the grasshoppers. This Criddle mixture now seems preferable to the poisoned-bran remedy that has given and still continues to give beneficial results, for it is less expensive than the latter and less likely to poison other animal life.

Co-operation.

Co-operation between farmers or ranchmen is of the usmost importance, whether the hopperdozer or poisoned baits be used. On some of the most extensive ranches the owners can protect themselves by reason of the great extent of territory that is under the control of a single individual, but among smaller holdings co-operation is very essential.

Forestalling Outbreaks.

The ranchman would style this "watching out for trouble." By this is meant the careful watching of the fields for the appearance of the grasshoppers. When these are found to be present, do not wait to see what they are going to do, but prevent their doing anything by putting into practice, before any damage has been done and while the grasshoppers are very young, whatever measures are to be used. It usually requires several days to poison the grasshoppers, and large areas can not be traversed with the hopperdozers in a day. Do not then wait to see what the grasshoppers will do, but see to it that by taking them at the start they are prevented from doing any harm.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Holtville reports a young boom in the dairy business.

Ranchers are cutting hay at Hemet. There is a very good crop.

Alfalfa growers about Los Angeles have been suffering from the cutworms.

Thermal reports a total of over forty-two cars of onions shipped this season.

Turkey raising is an industry of promise at Holtville in the Imperial country.

Riverside Chamber of Commerce is exhibiting stalks of oats more than six feet tall.

Ranchers of Anaheim are sending out a great cry for more help in orchard and field.

There is approximately 100,000 acres subject to reclamation in the Imperial Valley.

The average price for onions in the Thermal district is two cents per pound to the grower.

Oxnard reports the crop of beets doing nicely; the acreage will be smaller than last year.

It is predicted that the crop of beans in Ventura county this year will be greater than ever.

W. H. Faulkes of Valle Vista brought in to Hemet some alfalfa last week, six and one-half feet high.

The crop of hay about Oxnard is reported greatly reduced by the lack of the late rains which were expected.

Walnut growers about Saticoy report blight exceedingly heavy this year. The earliest nuts are reported an entire loss.

Extensive topographic surveys are being made in the Imperial country preparatory to the establishment of new irrigation lines.

Ventura county farmers are planning for an immense hay harvest, though it is claimed the crop, the country over, will be small.

Farmers having water rights in the Sierra Madre Mountains report the flow from springs and cienegas to be more profuse than for many years.

An immense submerged dam is being built near Ventura, which is nearly 1200 feet long and generally 30 feet deep before it found bed rock.

Bean planting is in full swing in Northern Los Angeles and Ventura counties. This is later than usual, owing to the cool and foggy weather of this season.

Moreno farmers are jubilant over new developments in that section which, it is to be hoped, will lead to much water, from new sources, being applied to their orchards.

The farmers southeast of Chino are hoping for an extension of the Salt Lake road through their lands to give an outlet for their products, give an outlet for their products, which are generally alfalfa and barley hay.

The Lompoc section has been visited lately by several cattle buyers and the prices quoted for cattle are exceptionally high, beef bringing 3 and 4 cents a pound, while pork is quoted at 8 cents. Sheep bring about $5 a head.

The cold weather of the Rocky Mountains has caused a lessened flow of the Colorado River, so that the amount of water passing Yuma at this time, which is approaching the flood season, is much less than that of last year.

A Los Angeles man named Wise has bought 5000 acres of land in Tulare county and will put it out to oranges. There is something in a name after all. If you have a little extra money our advice is, "Go thou and do likewise."

Order has been given from the United States General Land Office at Washington opening to entry a vast tract of land in the San Jacinto forest reserve. This, it is claimed, will give to settlers 129,280 acres; it will be subject to entry July 27. This is the largest tract ever opened in Southern California.

HORTICULTURE.

Redlands' rainfall amounts to 23.46 inches.

Corona reports extensive hay-making operations.

Ontario apricot growers are being offered $60 per ton.

Two orange-seed beds have been planted at Hemet this spring.

Nearly 3000 cars of oragnes is the output of Redlands at the present time.

Riverside has forwarded in excess of 4000 cars of oranges up to this time.

Extensive improvements are being made on the Chino ranch irrigation system.

Pomona men have filed on 100 inches of water at the mouth of Coble's canyon.

The apricot outlook for Elsinore is one of the most promising, and big prices are anticipated.

Corona reports 15.15 inches as its total rainfall to date. This is the highes rainfall for years.

The "Orange News" appeals to its readers to plant forests of camphor, maintaining it offers opportunities for wealth.

Planting of apricot orchards is reported to be more general in Southern California this year than heretofore for years.

There is a rumor that a syndicate of wealthy men is proposing to plant orange groves on the slope-lands of the Coachella Valley.

Orange county gardeners are finding great profit in raspberries, one farmer, near Garden Grove, having 100 acres set to these berries.

The famous "Little" lemon grove at Uplands has recently been sold. This is the grove that for two or three years netted its owner approximately $1000 an acre.

The fight between the ranchers of El Modena and the Irvine Water Company is being pushed by the ranchers combining and putting up a big purse to meet the expenses of the suit.

Newt C. Smith of Pasadena has bought land east of Hemet and has erected a barn and a large lath-house, where he will grow ornamental shrubbery and flowers for his Pasadena store.

The output of olives from California in a normal year is 7500 tons. This is pretty evenly divided between Northern and Southern California, the Northern part producing slightly more than half.

The packing-house of the Heber Melon Shipping Association was burned to the ground, while under construction, recently. This caused some delay in getting out the earlier shipments.

Riverside fruit growers are giving a liberal roast to a Redlands fruit-shipping concern, because of alleged forwarding of circulars, in which Riverside fruit was spoken of in a way to decry that fruit.

Some oranges delivered to packing houses have been thrown out on the account of injury to the ripened fruit by cutworms. It is claimed that one ranch at San Dimas had over 1500 boxes rejected because of this trouble.

The Cucamonga Vineyard Company is suing the San Antonio Water Company to prevent Ontario from pumping water from the Cucamonga springs for its domestic supply. This is an old-time suit of years' standing.

Colorado desert expects to yield about 1000 cars of cantaloupes this season; four years ago the same section yielded a great number of driving sand dunes. This change comes from hard work and the application of water.

A new department has been added to the State Citrus Experiment Station, at Riverside, by the addition of Mr. E. B. Babcock to the working force. Mr. Babcock's experiments will be confined principally to citrus fruit products' experiments; he will work in conjunction with J. W. Mills.

Northern California

AGRICULTURE.

A freak chicken, with four legs, has been brought forth at Porterville.

New artesian wells are being developed in the farming lands about Athlone.

Yuba county reports light yield of the hay crop, which is now being gathered.

Santa Clara County Grange met at Cupertino on the 18th and held an important session.

The Mardis ranch, near Porterville, was recently purchased by J. T. Hood, a banker of Arizona.

Exeter is receiving some fine horses and mules shipped in from stock ranches of the East.

Wheatland is a great hay center; hundreds of tons being shipped from Wheatland each year.

The California Experiment Station, at Berkeley, has a new sweet potato, for which much merit is claimed.

A petition has been presented for the formation of a new levy district in the northern part of Sutter county.

R. E. Laws, a rancher near Turlock, has constructed a sweet potato planter, which it is claimed is a great success.

Oakdale has 1600 acres of peas under cultivation and expects to ship 269 car loads of peas from that little town.

The trustees of reclamation district No. 70, in Sutter county, have a big shovel dredge at work strengthening the levies.

The Exeter Sun reports that some standing hay in that section may be burned off because of lack of labor to aid in its harvest.

The Big Meadows of Plumas county is the gathering place for many farmers who wish to take on outing in a restful place.

The Happy Valley Land and Water Company has fixed its water rates to irrigators for the coming year at the rate of 18 cents an inch.

The Lindsay Gazete carries an advertisement for a farmer who offers to sell his standing oats, barley and wheat at 75 cents an acre.

The floods destroyed this year's crop on over a thousand acres of asparagus land in the delta of the San Joaquin and Sacramento Rivers.

The fame of the Petaluma poultry industry has drawn from New Zealand several investigators, who are there looking into its methods of work.

Yuba county is having a serious time harvesting its hay crop, owing to teams and men being employed in extending the railway lines of that section.

Prof. Loughridge, of the State University, is analyzing the soil in the neighborhood of Exeter, and says the mechanical condition of the soil is of the best.

The papers in the San Joaquin Valley are, some of them, referring to the value of Lippia repens as a lawn builder and for holding up the banks of levies.

One of the features of the State Farm at Davisville is the live stock amphitheater, which is expected to afford meeting place for various live-stock organizations.

Woodland, Yolo county, is rapidly becoming a favorite field for breeders of fine horses. It is said to offer the best conditions for fine horse breeding of any section in the State.

Six hundred acres of bottom land below Yuba City have been leased to a Marysville company for the establishment of a fine new dairy. The company already has 200 cows in hand.

After experimenting with a small planting of hemp in the Sacramento Valley, it is now predicted that a large acreage will be planted another year, and some of the more hopeful ones of that section are looking for a linen factory in the near future.

HORTICULTURE.

Ceres is working for a new experiment station.

Dropping of pears is reported in many sections.

San Joaquin county reports a good crop of cherries.

Tehama is oiling the streets and planting shade trees.

New wells are being sunk in Zante Heights Tract, near Porterville.

A ton a day is claimed to be the output of strawberries from Turlock.

Modesto News reports two grape cuttings with six feet growth in six weeks.

Newcastle reports its fruit crop to be 100 per cent. better than it was last year.

Happy Valley, near Anderson, Shasta county, reports a big crop of peaches.

The Raisin Association and the Pacific Coast Seeded Raisin Company have disbanded.

The supervisors of Merced county have fixed the water rate at $1.65 for the coming year.

Ceres has an improvement club thoroughly alive to the advantages of a clean community.

The Sutter County Farmer reports an average fruit crop in the neighborhood of Yuba City.

Sonoma county small-fruit growers are receiving $50 per ton from canneries for blackberries.

Roseville, true to its name, claims to be the home of some of the most beautiful roses in California.

Globe, an orange producing section near Porterville, has shipped its last car of oranges for the season.

The Kermen News appeals for the planting more extensively of strawberries and other garden fruits in that section.

The water in the Pearson district is receding very slowly and will prevent some of the farming lands from being used.

A severe thunder shower stuck the community of Woodland last week, but more good than damage is claimed to be the result.

The citizens of Campbell are organizing for civic improvement and the placing of the roadways of their community in better shape.

The Butte county canal will be repaired from the damages of the storm last winter, so as to deliver water to irrigators by the first of June.

Modesto News is urging its Board of Trade to make an exhibit at the National Irrigation Congress, to convene in Sacramento in September.

Eight cents per pound is offered for dried peaches at Yuba City. A prediction is made that ten cents will prevail before the end of the season.

The Exeter Sun says fruit prospects in the vicinity never looked better; peach trees are loaded and promise of full crop; grape vines also promise large crop.

Oroville, with a hard-working improvement association, is planning for better roads, cleaner streets, shade trees, and other features that go with an up-to-date community.

Prof. Quayle, specialist of viticulture of the State University, has done some work in the Lodi section hoping to offer relief from the depredations of the vine-hopper.

The Valencia harvest at Lindsay is now on. It is reported that it will aggregate about 100 cars. Lindsay is practically the only Valencia shipping section north of Tehachepi.

The Board of Directors of the Turlock irrigation district met at Ceres and decided on purchasing a new dredger and making improvements on the system. The dredger will cost about $5000.

The cool spring weather has caused the snows to melt so gradualily that but little high water has prevailed along the San Joaquin and its tributaries; it has also held back the larger supply for later irrigating season.

Buy the World's Famous Egg Food No. 4

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Profit in the Poultry Yard

By FRANK H. THOMAS, Los Angeles, California

THE BANTAM FOWL.

THE breeding of bantams is often looked upon as a waste of time, energy, and money, as most people look at poultry breeding or poultry culture as a cold-blooded, dollars and cents proposition, and only keep poultry from the good that they receive from it, never stopping to consider the beauty of an even colored flock of thoroughbred fowls.

The art of bantam breeding (for we consider one, who by selecting, mating, and breeding can fix color and type, just as much of an artist as one who takes a brush and produces the same on canvas) is as interesting, profitable, educative, noble, and refining as any other art. Suppose we take up agriculture. The growing of beans, potatoes, and cabbage is not considered much fun, and one tires very quickly of the constant grind, of the dull monotony of straight rows, with little variety of color.

Let us come into the flower-garden and try our hand at roses, violets, or chrysanthemums, and we find the work much more difficult, yet how much more we enjoy our work; if we meet with difficulties, it only stirs us to greater care and study. Just so with the breeding of bantams, they are the flowers of poultry culture.

Money in Them.

Bantams have, from a monetary standpoint, all the commercial characteristics of the large bird except in size, and this is offset by quality and flavor. They cost less for feed and give a greater yield of eggs in proportion to the amount of food consumed than the larger breeds.

We find more bantams bred by the fancier and the city poultry breeder. This should not be; the conditions on a small lot are not, as a rule, so favorable for the raising of these little beauties as the larger ranch or farm.

We believe this line of poultry culture should be taken up by the market poultry-man as an excuse for getting his boy or girl interested in poultry; but by all means get good, standard bred birds of some popular variety, as they can be sold much more readily than common stock. Where you will sell mongrels from 50 cents to 75 cents per pair, you can sell thoroughbreds from $3.00 to $25.00 per pair and eggs from $2.00, $3.00, and $5.00 per dozen. A few of thoroughbred, well-mated bantams give tone to any poultry yard.

Varieties of Bantams.

There are a number of varieties, perhaps fifty all told; nearly all the larger breeds have their counterparts in a bantam! Most any variety will prove profitable and interesting to breed, and many varieties will be found on the Coast. At the late Los Angeles shows, there were over one hundred and seventy-five of these little pets exhibited and were the attraction of the show, and many good sales were made. The writer has in mind several large breeders of these pets who have added them simply because of their beauty.

Perhaps the oldest varity of bantams is the game, although there has been a great change of shape and carriage in this variety of late years. The exhibition game bantam of today reminds one very much of a jack-snipe in appearance.

Another odd breed is the Japanese, of which there are several varieties. We know the patience and time the Japanese give in anything they undertake; we are told that they will spend a greater part of their life in improving some particular flower. The Japanese bantam is a very queer fowl. History tells us that the shape was produced by taking a bird and confining it in odd-shaped boxes which compelled it to grow to suit their fancy. After fowls are thus confined and the desired shape is produced, they are very closely inbred until the shape is fixed.

One of the most beautiful breeds of bantams is the Sebright, comprising the Golden and Silver. This breed was originated over one hundred years ago by Sir John Sebright, and is the only fowl bred to-day, either large or small, with feathering exactly the same on both male and female. When we consider this, and how true they breed, we can realize to some extent the amount of hard work and study that has been done to perfect them.

The Goldens are a rich golden color with each feather laced with a narrow lacing of glossy black. In silvers, the ground color is a silver white, each feather evenly laced with a narrow lacing of rich, glossy black. Each should have a bright red rose comb, bay eye, and slaty legs; standard weight of cocks is twenty-six ounces; cockerels, twenty-two ounces; hens, twenty-two ounces; pullets, twenty ounces. The Sebrights bear confinment well, yet enjoy their freedom as well or better than the larger birds, and will roam a long way from home if given an opportunity. They are good layers and their chicks are quite strong and hardy, but care should be taken for the first four weeks.

The Cochin bantams is another popular variety, especially the Buffs, and in our mild climate of the Pacific coast are being used a good deal for hatching pheasant eggs, as phesants are not good setters, and the Cochin bantams are very faithful and excellent mothers.

There are many other popular varieties of these little pets that we would like to mention, but space forbids.

We hope the breeding of bantams will be taken up by many of our readers, and we are sure that those who try it will be well rewarded for their efforts.

AN EASTERN POULTRYMAN IN CALIFORNIA.

The Cultivator has a letter from Miller Purvis, editor of "Poultry," a beautiful monthly magazine devoted to poultry industry, published at Peotom, Ill., but now visiting his California ranch at Olinda, Shasta county. In it he expresses his satisfaction in California. He says:

"I came here three weeks ago and found the Cultivator a regular visitor and a gladly welcomed one. I had never been here before, having bought the ranch through a relative, and for that reason did not understand how valuable a publication the Cultivator is for Californian agriculturists.

"I am delighted with the country here in Shasta county. The fruit crops promise to be large. On Sunshine ranch the peaches, nectarines, pears and grapes are loaded. The almonds bloomed at the wrong time, and will not fruit this year. We have a few

cherry trees, which are loaded with fruit, and our 'truck patch' is growing finely.

I am preparing to add poultry and pigeons to the list of things produced here, and expect to have one of the show places of California before I call Sunshine Ranch complete.

We are preparing to experiment in growing fruits on the hillsides without irrigation. I have dug into the sides of the gulches and believe olives, grapes and other fruits can be grown with success, without using more water than the rains furnish. The plan I shall follow is to dig a hole of liberal size and depth, filling it to within eighteen inches of the top with the cobblestones that are so plentiful here. Over these I shall put the top soil and set the trees. I figure the holes will fill with water during the winter rains, and that the impervious clay will hold the water a long time, allowing the roots to reach down to it.

"Strawberries are a large crop here, but there are not many acres yet used for this fruit. The crop this year will probably run to 400 crates to the acre. Growers are getting from $1.25 to $1.50 per crate of fifteen-pound boxes at Redding and Anderson.

"I have just bought an incubator and expect to begin hatching at once, as it seems to me that poultry breeding must be very profitable in this country."

INCUBATING WITH HENS.

Circumstances sometimes make it necessary to raise chickens by the aid of the hen. While the Maine station does not like this method, it has practiced it, and at times has had as many as a hundred setting hens ranged in nests along the side of a room in two tiers. A recent tie-up in a barn was used as an incubating room and a platform was erected along the side next to the barn floor. The platform was raised three feet above the floor, was two and a half feet wide and fifty feet in length.

This platform was divided into fifty little stalls, each a foot wide, two feet long and one foot high. This left a wall six inches wide along the front of the nests for the hens to light upon when they flew up from the floor to take their places upon the nests. Each nest had a door made of lath at the front so as to afford ventilation. Each door was hinged at the bottom and turned outward. Across the center of each nest a low partition was placed so that the material from which the nest was made could be kept in the rear end.

For early spring use paper was put in the nest, then upon the paper an inch or two of dry earth was placed, and on top of this the nest proper was made of soft hay. At such periods as half a dozen or so hens showed a disposition to brood they were taken in from the henhouse and put on nests, each nest having a dummy egg in it. The covers were then shut up, whereat the hens within would appear perfectly content.

After a day or two thirteen eggs were placed under each hen and then the real business of the incubation began. Every morning as soon as it was light the setting hens were let out. They would leave their nests on their own accord, go out around, scratch, drink and pick up such food as they appeared to desire. Fifteen minutes at this was enough, and then the old hens would hurry back to their nests without the least urging.

If, during the afternoon during the early stages of the brooding, any hen came off the nest and showed a desire to get out she was liberated and another and more faithful brooder put in her place.

Here may be seen the efficiency of the double nest, because it gives the discouraged hen an opportunity to show her discontent without standing on her eggs and very likely breaking them.

There are many advantages possessed by the closed room in which to confine sitting hens. The hens are more easily managed and do not need to be watched so narrowly as when left to select nests for themselves, or when sitting in a room in company with laying hens. A room twelve feet square would be sufficient for any ordinary number of sitters, say fifty for instance. In fact the Maine Experiment Station would not recommend sitting hens for anyone excepting the small operator.

For the accommodation of a hen with chicks a close coop about thirty inches square is found the most feasible. The coop should have a hinged roof and a movable floor made in two parts so that it may be lifted out and cleaned; and the cleaning should be done at least once a day. This coop has a wire-covered yard attached to it on the south side. The yard should be four by five feet on the ground, and a foot and a half high. The frame of the yard may be made of 1x3 inch stuff and should be securely fastened to the coop. The wire on the sides should be of one-inch meshes, but that with two-inch meshes will do for the top.

A small run will do for these broods for the first few weeks; but as the chicks grow they will in time need more commodious quarters. Then the outer end of the run may be lifted sufficiently high for the chicks to run out and in at will. Such a coop will accommodate from 15 to 20 chicks until They pass beyond the brooding age. Then several broods may be combined and put in a portable house on a grassy range.

In all cases where a hen is put to hatch her own eggs or to brood another's chicks great care should be taken to keep the lice in check; for if ever these pests obtain a foothold they will ruin the birds. The free use of insect powder upon the hen and the careful working of the powder through the feathers to the skin is one of the most effective methods of destroying lice. Grease or oil applied to the head of the hen is effective in that part, but care should be exercised as to applying too liberally, especially in damp weather. The feeding of chicks raised by this method is about the same as those raised in brooders.—Maine Experiment Station Bulletin.

TRUTH ABOUT THE COW.

A worthy squire had a cow that always kicked and reared when milked. He decided to get rid of it, and, calling one of his farm hands, told him to take it to the market.

"Sell the brute," he said, "but mind you, tell no lies. I've been unlucky in my purchase, but that's no reason why I should deceive others."

Two hours later the man returned from market with a larger sum than the squire expected. "I'm sure you lied about that cow," he said.

"Not a bit of it," replied the man; "every time I was asked if she was a good milker, I simply said: 'You'll get dead tired of milking before you get all her milk."—[Exchange.

Don't feed the little chicks anything for the first twenty-four hours. Then feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seeds, meat, etc., in just the right proportion to make a full, rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and it will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keep it, and will not get it, send $3.35 for 100 lbs., freight prepaid by us to any point in California.

Are your fowls a little off—don't you want to tone them up?

West Coast Poultry Tonic

will do it sure. It is one of the greatest cures for ROUP and all kinds of colds.

Hen Fruit Pays—if you want more, feed

West Coast Egg Food

That highly nitrogenous poultry food, rich in protein, to keep the poultry in good health, and enable the hens to convert the surplus aliment into eggs.

Or if you want to make your own Egg Food use

EGG-MORE

which contains all the ingredients of West Coast Egg Food except the grains. If you are distant from Los Angeles it will be better for you to buy your grains at home, and add Egg-More as directed, which with good grains makes a perfectly balanced ration for all fowls over half grown and especially for the hens that should lay.

West Coast Lice Killer and Killamite (powder)

are most effective pest destroyers. Nearly all the diseases of poultry may be attributed to lice and mites. Don't let them get the best of you. Get the best of them. And did you know that Killamite is just as good for killing plant insects without harm to the plant. Testimonials of public gardeners and others. Try it on your roses. 25 cents and 50 cents sifting cans, express prepaid if your dealer won't get it for you.

West Coast Poultry Foods and Remedies

are the best made and, quality considered, the cheapest. If your dealer doesn't sell them, send to us. Booklet free. Send us names of 12 persons keeping poultry and we will send you free "The Poultry Manual" by those high authorities F. L. Sewell and Ida E. Tilson, profusely illustrated.

This is a photo of 201 Gophers killed in one day on a 10-acre field with one bottle of

BILLE'S GOPHER POISON

Endorsed by Agricultural colleges and Experiment Stations. It it most attractive to gophers, squirrels etc., and sure death to them. We have bought the patent right for this section and are selling at the eastern prise. Money refunded if not as represented—so printed on the bottle. If your dealer does not keep it send $2.50 for two bottles, express prepaid by us—not less than two bottles.

Confident that a trial will prove beyond question that the best condition powder made is

West Coast Stock Food

We will send to new customers one 25-lb.

$3.00 Pail for $2.00

and will prepay the freight to any point west of the Rockies. Not more than 50 lbs. to each one, and we reserve the right to withdraw this offer without further notice. No cheap premiums, no gaudily colored pictures, but a legitimate business offer to induce a trail, hoping to add many steady customers. Feeling sure that a trial of the goods is the very best advertising.

No strings to this offer. Just send us your name, the freight station to whch you want the goods shipped, mention this paper, and we will do the rest. Send money order or check with your order, and if every thing is not exactly as represented your money will be refunded.

WEST COAST STOCK FOOD has for many years been a standard condition powder in this section. See our full page adv. in the March 7th and 28th issues of this paper or send for circular with testimonials.

RHODE ISLAND REDS.

Poultry keepers are turning their attention to Rhode Island Reds. There are some very practical reasons for this, one of which is that they are a double purpose fowl. They are good layers and they are also a fine table bird.

The experience of a poultryman, given in the Poultry Advocate, demonstrates the utility of the Rhode Island Red as a bird for general purpose. This man writes:

"The Rhode Island Reds are the practical poultryman's fowl, they are a new breed to a great many fanciers, although they have been bred in the state of Rhode Island for about forty years. In 1905 the Reds were shown at the Ontario, Guelph, for the first time. There not being a class for Reds, they were shown in A. O. V., and if I am not mistaken only six Reds were shown. At the Ontario, Guelph, 1906, there was a class of 64 Reds, which goes to show that Reds are coming to the front very fast and growing popular. Why? Simply because they are a practical fowl, very hardy and vigorous, and are noted as great winter layers. Their eggs will hatch a large per centage of strong chicks at any season of the year, and I believe they are the coming fowl for the farmer to raise.'"

KEEPING THINGS CLEAN.

Too much cannot be said about the cleanliness of the poultry house and lots at this time of the year. The house should be cleaned at least once each week. If things are arranged properly the task need not be a very difficult one.

Every sanitary hen house should have movable roosts. The ladder and roosting poles are attached to a frame which is detached from the floor and the device can be moved at will, either when the house is being cleaned or the keeper is fighting pests. Nests may be so attached to this roost that they too can be removed from the building and disinfected. When the old-style roost has so many cracks and crevices in which the insect pests can hide, the efforts to exterminate them are not effective.

In addition to the movable roosts, the poultry raiser should have a spray pump to effectively reach every part of the interior of the house which may be infested with mites. If fruit and flowers are raised in connection with poultry, a hand sprayer is needed nearly every month in the year.

VALUE OF HEN MANURE.

Some one has estimated that the manure from one hundred hens carefully secured and applied to concentrated crops as truck or fruit will pay for the food consumed aside from the waste food picked up about the farm. No doubt this statement is true, though most poultrymen offset manure against care of fowls and figure in the cost of food under expense. The value of hen manure in replacing commercial fertilizers which would otherwise have to be purchased is considerable, as shown in the following tables.

One ton fresh hen manure contains
Water, 1180 pounds.
Nitrogen, 28 lbs., at 17½c.....$4.90
Phosphoric acid, 19.8 lbs. at 6c..$1.19
Potash, 6.4 lbs., at 6c..... .90
Total value $6.47

One ton dried hen manure contains
Water, 149 lbs.
Nitrogen, 36.4 lbs., at 17½c....$6.37
Phosphoric acid, 44.2 lbs., at 6c.. 2.65
Potash, 22.2 lbs., at 6c..... 1.33
Total value $10.33
—Successful Farming.

HARD BOILED.

We find in the experience of almost all writers of poultry literature, they say, "Feed the young chicks hard boiled eggs." This may be all right, and the chicks may thrive on it, if the eggs are properly boiled. There is scarcely anything as indigestible as a hard boiled egg unless boiled for about thirty minutes. We have never yet been able to see the theory of hard boiled eggs for young chickens, any more than of hard boiled eggs for babies. The yolk of the egg is absorbed by the young chick just prior to exit from the shell and serves as feed for it for from twenty-four to thirty-six hours, and if you must feed young chickens eggs, feed them raw, as this is the more natural food. The first fluid that comes from a cow's udder after the birth of a calf is not milk, but a watery substance peculiarly adapted to the calf's stomach, and we never hear of a dairyman feeding the calf hard boiled milk for its first feed, and we believe one is as reasonable as the other.

Breeding fowls should be kept in a condition neither too fat nor too lean, and they should be fed on a variety of ground grain with plenty of bulky proteids. They should have access to sharp gravel at all times, calcareous matter for egg-shells, charcoal to purify the crop and stomach and aid in digestion, with plenty of pure water to drink at all times, and with plenty of exercise.

EGG INFORMATION.

Duck eggs seem to have the thinnest shells, being about 10.6 per cent. of the weight of the egg.

The average of thirty-four samples of hens' eggs gave 11.2 per cent for shell.

Turkey eggs ran slightly above hen eggs in this respect, having an average of 11.4 per cent. of the whole weight.

The shells of goose eggs average 12.8 per cent. of all.

Guinea fowl eggs should be unusually strong, as their shells form 14.4 per cent. of their weight.

The whites of the eggs in proportion to their total weight ran: Goose, 52.6; duck, 43.6; guinea, 53.6; turkey, 56.5.

The proportion of yolk to the whole egg ran: Guinea fowl, 32; duck, 33; goose, 34.6; turkey, 30.1.

Fowls need meat. Experience has proven that nothing will revive dormant hens as will a little cut meat or green bone. Get what the butchers call beef-scraps, and if you have no bone-cutter, cut them up with a sharp hatchet or ax. In some places these scraps can be had for the mere asking, while some butchers ask one cent a pound. If some small animal is accidently killed and is not diseased, give it to the hens, and they will surprice you in the way of shelling out eggs. Lambs and calves that are born dead or are killed at birth, make cellent food for hens. Hens fed on meat lay so well that they will hardly sit when you want them to. In France the large poultry-plants buy old horses and feed the flesh to their laying hens, and they find it very profitable.

Never be deceived and feed your hens because they run after you every time you appear, as it is due to the education you have given them, being only a habit. Make them work; an idle, lazy hen wil not lay eggs. When you notice her scratching and foraging you will find an egg in her nest.

The Ornamental Garden

By ERNEST BRAUNTON

THE WINDMILL PALM.

FOR general planting throughout the Pacific Coast no palm exceeds in value the Wind-mill, or Chusan, palm (Thachyearpus excelsus). With us it is perfectly hardy in any locality, even where snow falls freely each winter and the temperature occasionally drops 18 or 20 degrees below freezing. It thrives in England as far north as London, and is quite common in the milder parts of Ireland. It is native to China, India, and Japan; in the former country reaching as far north as Napong.

Aside from its hardiness regarding cold, it withstands more rough treatment, in every way, than any other species; it is one of the easiest to grow, as it thrives in any soil, and after being once established does not seem to note the water supply except in the amount of growth. Its leaf stems are short and wiry, the leaf proper tough and leathery, not easily damaged by the winds even where the more common species have their leaves whipped into ribbons.

Though one of the most ornamental (perhaps the best) of all fan palms, it is also very useful, especially at home, where it is put to many uses. In China and Japan the fibrous covering of the trunk is mixed with plaster, as we use hair, while the leaves are in great demand for plaiting palm hats. It is said that cordage prepared from the leaves will not decay in water. Its use as an ornamental is sometimes objected to by reason of its growth being somewhat slow, yet it is more responsive to fertilizers and a sufficiency of water than any of the fan-leaved section, so that its progress lies largely in the hands of the grower. In height it is not classed with the giants of the family, as it but seldom attains to more than thirty feet.

This genus (Trachyearpus) contains three other species, and one of these has the same native range as our subject, the other two hailing from the Himalayan region. The four species are strangely divided in appearance, one species in each range having the ends of the leaves quite pendulous, while the other two have the leaf-tips straight. The two from the Himalayas have trunks richly covered with the old leaf-sheaths and fiber, while the others have beautiful smooth, polished trunks. Both in the United States and Europe they seem to mix freely, and the intermediate types are so common that the specific differences are well-nigh lost. Those desirous of obtaining this palm from nurserymen will generally find it for sale under the name of Chamoerops excelsa, as it closely resembles that family.

FLOWERING EUCALYPTS.

Our most showy eucalypt when in bloom is the scarlet flowering gum (Eucalyptus ficifolia,) which always gives some shade of crimson or scarlet. We also have a very showy white-flowered species (Eucalyptus calophylla,) which is too little used. It is more handsome than the "robusta," so much used as a street tree, and is, in fact, superior in every way. One who wishes to experiment with producing a pleasing variety of colors and shades, in the flowers of these trees, may find a very enjoyable and interesting diversion by planting the two first named trees together harvesting and planting the seed and noting the result. He will find in the second generation every shade from white to crimson, some of them vying with the rose in beauty of coloring.

CYCLAMEN.

Everyone having a shady corner in the garden, with a light, well-drained soil, should grow a few cyclamen, "shooting stars," or "Persian violets," as they are variously called. Except for a short season during the heated spell they bloom more continuously than any other bulbous plants. In many gardens these exquisite little flowers may be seen in abundance, but some make the mistake of planting the bulb or corm too deeply; one-half of it should remain above the soil. Water constantly, yet keep good drainage else the bulbs easily rot. The colors range from white to a rich purple, often beautifully striped or variegated.

FOUR REMEDIES FOR APHIS.

1. Dissolve 1 pound of whale-oil soap (or any good fish-oil soap) in 8 gallons of water. Spray the lice thoroughly or dip the parts containing the lice into the liquid.

2. Steep 1 pound of tobacco stems, or good, clean tobacco dust, in 4 gallons of water for two hours; allow to cool, and apply as in preceeding case.

3. Dissolve 1 pound of soap in 1 gallon of boiling water; while boiling hot add two gallons of kerosene (away from the fire) and emulsify the whole by pumping it violently, through a spraying nozzle, back into the vessel containing it for a few minutes. This will make a stock solution sufficient for 30 gallons of spray matteial. Apply as in No. 1 above.

4. House plants may be dusted freely several times, two or three days apart, with Pyrethrum, commonly sold as Buhack, or insect powder.

Seed-growing, while one of the most scientific of all branches of horticulture or floriculture, is also one of the most expensive. A man must not be naturally inclined to any branch of this profession, but he must be thoroughly experienced before he can safely venture into this difficult field. The bulk of the vegetable seeds raised in California consist of salsify, lettuce, peas, beans, onions and beets, while in flowers sweet peas, verbenas, asters, poppies and hollyhocks are staple products.

The great California seed belt begins in the Santa Clara valley, about fifty miles southeast of San Francisco. In all its branches the seed industry in California gives steady employment to 3,000 persons. The wages of skilled or scientific help are very high indeed. Some of the most expert men in the seed line are employed in California, and the wages go all the way down to the seed-picker, who is able to earn from $1.35 to $2 a day.

They change their sky, not their affections who cross the sea.

The pitcher that goes often to the well is sure to be broke at last.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Bugs and Peanuts.

My cabbage plants are being ruined by plant lice. Am using sulphur on them, but they seem to thrive on it. Have to pick each one off separately and kill it with a club. How often should peanuts be irrigated?.

What is best to use on melon vines for striped beetle? Last year used "Lee's Insect Powder," but it killed all the large leaves, so made my melons late.—S. M. O.

The only thing that you can do with your cabbage lice is to spray with a whale oil soap mixture. The plant lice are sucking-insects and anything you put on the surface is not eaten by them. The kerosene emulsion is the easiest to make and is effective. Take three ounces of soap, three pints of sour milk or water and three pints of kerosene. Heat and pump through a hand pump for about fifteen minutes. Make this up to fifteen gallons and spray it on the bugs.

It is dangerous to irrigate peanuts after they begin to vine when the land is heavy enough to bake. The land should be kept well cultivated till planting time and should retain the moisture clear through the season.

Use a dust spray of Paris green for the striped beetles.—J. W. M.

Leaf Curl.

Inclosed with this are a few leaves taken from peach trees set last year.—L. D. Holtzclow, Greenfield.

Your trees have the peach Leaf Curl and the trees should be sprayed with Bordeaux mixture during the winter. That will stop the trouble.—J. W. M.

Lime for Oranges.

I would like to know how much lime, air slacked, to use on my orange grove? It is hard clay land and does not take water well. Also how much should I use on nursery stock, peaches and almonds.—Subscriber, Orland.

Try about 500 pounds per acre. If it proves to be of much benefit, follow it up when you think the land requires it again. You might try double that amount on a fraction of an acre, that is make the application equal to 1000 pounds per acre.

Remember that lime adds no fertility to the soil, simply makes heavy soil easier to handle and makes the elements more available, so that fertilizers must be used with it. This is especially true of potash.—J. W. M.

Gypsum for Orange Trees.

I have a young orange orchard planted last spring and I have some gypsum that I formerly bought for sowing on alfalfa. Will the gypsum be good to sow around the roots of the young trees?—J. F. H., Lindsay.

The gypsum will not injure your trees and will perhaps do as much good as lime would. Ten pounds per tree would be about the right amount. First, used in your stable as an absorbent and then taken to the orchard in the manure, will be a still better way of getting the fullest benefit from gypsum.

Flavor of Melons.

Will you please state whether pumpkins and water melons will mix, Some people say the fruit will mix the first year they are planted together, and others say it is the seed that will mix. C. V., Acampo.

Your question is one on which there is diversity of opinion. Botanists claiming that the flavor of melons is not affected by nearness to pumpkins or cucumbers, but that the seed would be of no value for planting. But as a rule the practical melon grower prefers to grow his melons away from the plants mentioned, under the claim that the flavor of the fruit will be very materially lowered.

Remedy for Aphis.

Will you please tell me how to get rid of a small green louse which has come upon nearly everything in my vegetable garden. I have sprayed with a solution of Paris green; 1 teaspoonful to 2 gallons of water. This does some good, but hurts the leaves of the beans.

I like your paper very much indeed; it is both useful and entertaining; I consider it the best of all the many agricultural papers I have ever seen.—E. D., Orosi.

The small louse of which you speak is doubtless the aphis, or plant louse, which would not be affected in any way by the Paris green which you used. The slight advantage which you secured by spraying with the Paris green was only by the knocking off of the insect from the vine and its inability to crawl back on it to do the plant any injury. In another column of this issue you will find an article "Four remedies for Aphis," also another, "Kerosene Emulsion" which is good.

Bear in mind, to understand spraying and to do it intelligently, you should know the life habit of the insect which you wish to destroy. One class of insects are supplied with jaws, or manibles, and eat the leaves; another class, of which the aphis is a member, do not eat the plant tissue at all, but by the use of their sucking tube, which is inserted into the plant tissue, the life-giving juices of the plant are sucked out. Hence you will see they must be destroyed by an application to their bodies, as they will never be poisoned by any Paris green application. The remedies referred to will give you relief, or even the use of the hose, where you have water under pressure, will knock them off the plants and give temporary relief.

CARE OF "IN FOAL" MARES.

Attention to the condition of in-foal mares should now be the care of every breeder, but by adopting the expression attention is not intended to imply that the animals should be overfed any more than that they should be starved. The great object to have in view is to keep the brood mare in such a state of health that whilst she is able to produce a sufficient amount of nourishment for her unborn foal she does not become too fat herself. An over-fat mare is apt to slip her foal, or else have an unnecessarily bad time of it when foaling, and hence the necessity that exists for watching her condition, and attending to the requirements of each mare as they arise. Mares of liberty can, of course, obtain a sufficient amount of exercise, but those confined in boxes ought to be taken out daily. Indeed, there is no objection to working an in-foal mare up to within a week or so of her foaling, provided, of course, that she is taken along slowly and not asked to do too much, as over-exertion may lead to serious results. It is best to give all in-foal mares a little grain towards the end of their time, but for the first few months, if she is out on good land, the grass will supply her with quite sufficient nourishment. Should the mare be in a box it is necessary that the rule for constant feeding should be rigidly enforced, for a long abstinence from food is calculated to upset her.—The Horseman.

Ed Schwacofer of Hemet took $1100 worth of potatoes off 6 acres without any fertilizer, last spring. He, with a great many other ranchers on the Hemet tract are using fertilizer on their potato ground this spring, and hope to double the crops. Never have potatoes made a better stand than this

San Fernando hay buyers are active, or would be, if they could offer the price, which farmers are demanding; most of them holding for $15 per ton for the new crop.

FRIENDS OF GARDENERS.

The experts of the Department of Agriculture have discovered a new use for skunks, also for toads. As a grasshopper exterminator they have no equal.

By many it has been generally supposed that the toad had no excuse at all for living, and that the skunk, despised and shunned by society, was valuable only to the extent of what his pelt would bring on the market or in the lard that his fat would produce.

No greater mistake could have been made. Barnyard fowls, blackbirds and meadowlarks must take back seats. Even the red-headed woodpecker is out of the running.

This information would be received with great joy in Kansas, North Missouri and wherever grasshoppers devastate grain fields.

It is only necessary now for a farmer who has a field he wants to rid of grasshoppers, to go out and gather up a few skunks and turn them loose in the insect-infested area. This task might be delegated to the hired man. At any rate the skunks will do the rest.

"Skunks are very fond of grasshoppers and are esteemed by the Bureau of Biological Survey as the most useful of mammals," said the government experts on such matters. "They, therefore, deserve protection rather than destruction by the farmer."

TEETH OF HORSES.

In a discussion of this subject a horseman of much experience says:

Decaying teeth are not uncommon in horses. This condition is usually indicated by a fetid discharge from the nostrils or a fetid breath. In some cases difficulty is experienced in locating the diseased tooth, but when the disease has advanced to that stage in which it can be located, it must be extracted.

Wolf teeth (those small, supernumerary teeth, which appear in front of the first molars in the upper rows) are generally supposed to have an injurious effect upon the eyes. This is a mistaken idea. They seldom do any harm unless they are large and in such a position that they interfere with mastication; but being supernumerary and having no function they should be extracted. The somewhat common habit of knocking the crowns off should not be followed. They should be drawn with a pair of forceps. We repeat that sufficient attention is not given to horses' teeth, and that a dollar spent for having them dressed is usually a good investment, while a bungling job does more harm than good.

HAWAIIAN REPORT.

We acknowledge the receipt of a volume "Third Report by the Board of Agricultural Commissioners and Forestry of the Territory of Hawaii" from the Hawaii Promotion Committee.

The report has matters of interest for Californians. Amongst the reports is one from our old friend Alexander Craw, which shows that he did not escape from all the bugs in going to the islands.

The Report will be mailed on application to H. P. Wood, Secretary Promotion Committee, Honolulu, Hawaii.

The Escondido Creamery is claimed to be one of the most prosperous institutions of its kind in San Diego county.

Fullerton cabbages have advanced $3.00 a ton recently, and they are now commanding $17.00 net to the growers.

BERMUDA GRASS IN FLORIDA.

THERE is no doubt that Bermuda grass makes an excellent pasture, perhaps it is all that is claimed for it by the Tampa Times, but there are some who prefer St. Lucie grass. This, however, is not so very different from the Bermuda, in fact it is only a sub-variety of Bermuda.

The Times has at different times devoted much space to endeavoring to install into the minds of the Florida farmers that of all the grasses indigenous to the soil of the United States, Bermuda grass is the grass best suited to Florida, and that when once sodded down it will supply in this climate grazing pastures equal to any to be found in the country, and it is, therefore, with considerable pleasure that in conversation with N. A. Callison, the manager of Spring Park, the largest and best equipped stock farm in the State, that gentleman entirely concurred with the expressions of this paper, and announced that he was rapidly planting all his pastures on the farm in this grass.

Mr. Callison stated that Bermuda would eventually become to Florida what the blue grass was to the stock regions of Kentucky and Tennessee, and that with the gradual extension of these pastures as the people began to realize their worth, the State would eventually become one of the great stock producing sections of the country.

Mr. Callison pointed out the ease with which a pasture of this kind could be produced, placing its possession within the possibilities of the poorest farmer in the State, and to the fact that it was never really killed in the coldest weather, the young shoots putting out next to the ground with the first shower after a killing frost.

Another point in favor of this grass is its ability to hold moisture, making it that much more palatable to stock, especially cattle, and this feature has probably been noticed even by those who are not connected with agriculture, but spend their lives in the towns, as a Bermuda grass lawn will hold the moisture of a heavy dew until a late hour in the day.

But Mr. Callison is not the only cattle man in the State who has finally decided that Bermuda is the grass which is needed to raise calves, pigs and colts in the State of Florida. John Moody has been planting it for some time on his farm at Brandon, and W. L. VanDuzor and other progressive stock men of that great cattle country—Osceola county—are also rapidly sodding down all their permanent pastures with this once much despised grass.

Some farmers have set up the plea that on account of its creeping nature stock which graze regularly on it devour a large quantity of sand along with the grass, with disastrous results, but this condition of affairs only prevails, according to the best authorities, where the animals are kept on too small a pasture, giving the grass no opportunity to recuperate itself. Even under these circumstances it does not become extirpated, its powers of vitality being wonderful, but at the same time it is evident that to obtain proper results from it the pasture should be divided into fields to which the stock may have access in rotation.

Furthermore, it is advised by those who have made a study of the subject, that at stated intervals it should be liberally fertilized with bone meal, which not only enables it to make a sturdy and vigorous growth, but at the same time enables it to incorporate those ingredients for the making of bone and muscle which are so essential in the food of all young and growing stock.

It is unforunately a fact that the glamour and splendor of the orange and other citrus fruit displays at the State fair attracts the attention of the majority of the visitors but to the man who is anxious to see the State of Florida built up on a solid foundation, a fine display of grass or hay will have more weight. Given a grass no country can fail to produce a living for its inhabitants, the majority of the necessities on which man depends for his existence, obtaining their direct nutrition from grass, and it is for these reasons that the Times hails with delight every stockman who is making an effort to improve the grass conditions of the State, and who is willing by experiments, no matter how small, to add his share to the upbuilding of the State.

When the railroads cease hauling baled hay from the north and west into Florida by the carload, the State will enter upon a new era of prosperity, such as she has never seen, and from present indications Bermuda grass seems to be the password by which this desirable condition is to be obtained.

TANNING A SHEEP PELT.

Sheep skins make fine robes when they are tanned in a proper manner. When the pelt is removed from the sheep it should be thoroughly salted on its flesh side and rolled up to cure, so it will not become putrescent and give off a bad odor. When it is thought best to tan it should be unrolled and the surplus salt removed; then wash the pelt in a strong soap suds and make it as pliable as possible, after which all the surplus flesh should be removed so that nothing but the skin and the wool remain. It is thought that the old-fashioned lye soap is better for this purpose than any other. This may be a matter largely of opinion, however.

When washing the pelt it should be thoroughly worked by hand or rubbed upon a washboard. When thoroughly washed and all the water removed a preparation of equal parts of pulverized alum and borax should be well rubbed in on the flesh side. The alum acts as a stayer to hold the wool fibers from coming out and the borax helps in the tanning process. These substances will be more effective when dissolved in warm water and applied in liquid form. To prevent rigidity of the skin it should be thoroughly worked by hand until it is perfectly dry.

ANNUAL MEETING.

The seventh semi-annual meeting of the Counties Committee of the California Promotion Committee will be held on Friday, June 7, 1907, at Petaluma.

The theme of the meeting will be, Forestry and Irrigation in California. Addresses will be made by men from different parts of the State, competent to treat the subject from a broad standpoint. The discussion will bring out the importance and value of forestry and irrigation to all interests, and a campaign will be inaugurated for the betterment of conditions in this regard.

It is expected that this meeting will stir up a general State interest in the National Irrigation Congress, to be held in Sacramenta in September next.

Arrangements have been made with all railroads for fare and a third for the round trip, on the receipt certificate plan. The Pacific Coast Steamship Company has also granted reduced rates.

The Burnett school, on the Monterey road, in Santa Clara, is becoming noted for the enterprise of the children in raising a beautiful flower garden.

IT'S PENNY WISE.

Policy to set out a good tree, costing good money and then let the sun burn the bark or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Manufacturing Company, 2124 Willow St., Los Angeles.

SURE CURE FOR PILES

ITCHING Piles produce moisture and cause itching. This form, as well as Blind, Bleeding or Protruding Piles are cured by **Dr. Bosanko's Pile Remedy.** Stops Itching and bleeding. Absorbs tumors. 50c a Jar at druggists or sent by mail. Treatise free. Write me about your case. DR. BOSANKO, Philada, Pa.

Household Department

THE OTHER FELLOW'S JOB.

There's a craze among us mortals that
is cruel hard to name,
Wheresoe'er you find a human you
will find the case the same;
You may seek among the worst of
men or seek among the best,
And you'll find that every person is
precisely like the rest.
Each believes that his real calling is
along some other line
Tnan the one at which he's working—
take, for instance, yours and mine.
From the meanest "me-too" creature
to the leader of the mob,
There's a universal craving for "the
other fellow's job."
There are millions of positions in the
busy world to-day,
Each a drudge to him who holds it—
but to him who doesn't, play;
Every farmer's broken-hearted that in
youth he missed his call,
While that same unhappy farmer is
the envy of us all.
Any task you care to mention seems
a vastly better lot
Than the one especial something
which you happen to have got.
There's but one sure way to smother
Envy's heartache and her sob;
Keep too busy at your own to want
"the other fellow's job."

—Success.

QUEEN ESTHER'S PETITION.

THERE was a deep scowl on the chief clerk's face as he ran his eye over the special delivery letter he held in his hand. Impatiently he seized a pen and commenced a reply:

Washington, D. C., July 12, 190—.

Dear Senator: It will be impossible to reinstate your man, Williams. I have promised the place to Dawson. You know Dawson yourself, and there is no better man. I regret—

The door of the chief clerk's office was pushed gently open.

"Well?" he exclaimed without raising his eyes.

"Please may I come in?" asked a sweet childish voice.

He glanced up and with astonishment laid down his pen. On the threshold was a little girl with laughing blue eyes and sunny curls and the eager face was flushed with July sun.

"Well," he said gruffly, "aren't you already in?"

"Oh, yes," replied the child, "but your guard—"

"The messenger?"

"Yes, the messengers. They said you musn't be 'sturbed, but I 'splained that I am Queen Esther, and had to see you on most 'portant business."

"Queen Esther?" he asked.

"Not truly, my real name is Alice Williams—but I'm pretending I'm Queen Esther, and"—with a deep bow—"you are Ahasuerus!"

"And I'm come to save my people," she went on. "Not a sure 'nough nation, but my mother. You haven't asked me to sit down," she added.

With unwonted gentleness he stooped and lifted the child to his desk.

"Now, King Ahasuerus," she said, "we can talk more comfo'bly, but, first, are you a Medunpersian?"

"I think not," he answered slowly.

"Why?"

"I'm glad," she replied, "'cause as you aren't you can change your mind about 'smissing my papa."

"Did he send you here?" he demanded.

"Oh, no, no!" said the child; "he wouldn't never have let me come; nor mother most of all. I—I runned away! But won't you please promise you'll never tell?" she asked beseechingly.

"Yes, I'll promise—"

"Cross your heart?"

"Cross my heart."

"Father said you were the one to come to, but he'd never ask a favor of you. I couldn't let mother starve, so I thinked if you weren't dreffel cross I'd ask you myself, and I runned off, and—I think you're very nice."

"Thanks, Queen Esther."

"Yes, though you don't smile very much, but p'raps you've your own troubles. I symperthize with my mother, you know."

"How is your mother?"

"You see, she's had nervous persuation ever since father lost his money, and she mustn't never be worried, and," shaking her little finger at him, "you've gone and worried her!"

"I'm sorry," he muttered, as though he were but seven, and his accuser thirty-five.

"You see, father doesn't talk 'bout nothing but the for-tune he lost, and sometimes he drinks to forget it."

"Cowardly brute!" he muttered under his breath.

"So course, there's nobody to think about mother but me, and yesterday —"

"Well?"

"Father said the rent was due tomorrow and we haven't any money at all, and there's no use for him to try 'cause everybody's 'gainst him.

"And then mother cried, and she mustn't do that 'cause it makes her worse, and if she gets worse all the time she'll die!"

"Well, then, Queen Esther, what is your petition?"

"Why, you just put father back again! Won't you please?"

"It is one of the best places in the office, and Dawson must have it," he repeated to himself, but the pleading voice went on:

"Please, Ahasuerus, I just want you to let him stay till I'm big enough to take care of mother. It won't be so dreffal long."

"As soon as you are big enough to do that," he answered, smiling, "you'll go off and marry some rich man—"

"No, no," she interrupted; "that's a orful thing to do!"

The chief clerk had bowed his head on the desk.

"I'm 'fraid you're dreffal tired of me," slipping down, "and I must be going now or mother'll miss me."

"Goodby, Queen Esther," he said. "I will think your petition over and grant it if I can—and I thank you for coming."

"You are welcome," she replied sweetly. "But mother must have been mistooken when she said you hated her. You're so kind, I reckon you couldn't hate anybody, could you?"

"At least, not your mother," he answered, smiling down at her.

"Nobody couldn't do that. Remember you musn't never tell I came 'cause you crossed your heart, and that's more than a Medunpersian. Goodby." And the little mouth was put up to be kissed.

The chief clerk rose, and walking over to the window, stood gazing out for a long time. Then he turned and rang for his private secretary. To him he dictated a letter:

Washington, D. C., July 12, 190—.

Dear Senator: Yours of the 12th instant has been received. I take pleasure in informing you that J. R. Williams has today been reinstated.

Very truly yours,
John E. Mitchell, Chief Clerk.

"God save Queen Esther!" he muttered as he rang for a messenger.—Boston Post.

CARING FOR GLOVES AND RIBBONS.

A white glove should never be worn more than once without cleaning. If it is cleaned promptly after each wearing it can be used indefinitely, and the best way to remove a fresh stain is to dip a tooth brush in gasoline and rub the glove until clean, then rub dry with a piece of soft flannel.

Kid gloves of any color may be cleaned with gasoline, but the cleaning must never be done in a room where there is a light or fire. Put them on the hands and wash them in a bowl containing a little gasoline, using it as if it were water, and as if washing the hands. Rinse in clear gasoline and keep them on the hands until nearly dry, then pull them off in the proper shape; pin them up in the air to dry, and they will be unfaded and as soft as when new.

The tidy girl takes pride in her washable white kids, and always washes her own silk and lace gloves in summer.

The best way to wash the white kid gloves is to wash them on the hands in a strong suds of white soap to which a teaspoonful of borax has been added, and a little of the borax dissolved in the second and last rinsing waters will prevent the gloves from becoming yellow. White silk gloves are washed in the suds as if washing a handkerchief.

When ribbons have become wrinkled they can be freshened by dampening slightly on the wrong side, and then if they are pressed smoothly over a piece of white table oilcloth, they will need no ironing.

Black ribbon can be freshened by sponging with well strained cold coffee, and colored ribbons can be cleaned by putting them in the warm borax suds and allowing them to soak for fifteen minutes. Then lay them on a clean board and rub them gently with a soft brush until clean. Rinse out the suds in clear warm water, then wind them smoothly around a quart bottle filled with boiling water. If the ribbons are dried in this way they will need no ironing and they will look as clean and fresh as new ribbons.—A. M. H.

Now, girls doesn't that look good to you? It's a hint from a Kentucky subscriber of the Cultivator, and will, we trust, cause some of our California girls to return the compliment by sending in some hint that will aid in personal neatness.

By the way, let's start a Personal Neatness Club and have a meeting every week in the colums of the Cultivator.

Write Mrs. M., Household Department, care of Cultivator. 115½ N. Broadway, Los Angeles, and give your opinion and at the same time send along a hint.

Where do you keep your gloves when they are cleaned? Are your handkerchiefs tucked away "any old place," or where do you keep them? Where do you tuck your "combings" or do you leave them in your comb or brush? Do you have a cozy place to tuck away things and know where that place is, or do you say: "Mother where is my—?" Do other girls look in your room and say: "Well, ain't this nice," or don't you take other girls to your room?

And—oh, well, you konw, just send in some hints like Miss A. M. H. has.

"Bridget, did you mold the bread, as I told you?" "No, mum; I put it in that damp cupboard. Last week's bread molded itself in there, an' what's th' use of takin' extry trouble?"—[Cleveland Leader.

RHUBARB RECIPES.

Rhubarb, or pie-plant, has a large sphere of usefulness; and is quite as delicious as many other things. Few cooks, however, prepare it in a variety enough to have its value really appreciated.

Cut tender stalks that are of good acid flavor, wash and cut into one-inch pieces; place in a granite kettle and add two and one-half cups of granulated sugar to one quart of cut pie-plant, cover closely and place on the range where it will cook slowly. It requires no water; stir occasionally to make sure that the sugar is being dissolved by the juices of the rhubarb. When cooked clear, it is done. This is delicious served as sauce, or as a filling for cake; it is also nice served with tapioca as a substitute for apple.

If rhubarb is canned, it certainly will find acceptance. It can be cooked by the above method, then sealed in sterilized jars, or it can be canned by the cold water process. We have tried this last method at the Colorado Agricultural College and found it to be very successful. The following is the method which we employed:

Pare the rhubarb and cut into one-inch pieces. Pack in a jar, place under the cold water faucet and let the water run for about twenty minutes, then screw on the cover. Be sure to have the jar, lid and rubber thoroughly sterilized before using.

The following are some other recipes which have been tried and found to be excellent:

Pie-plant Preserves.

These are fine and are made similarly to the first recipe given, except the same weight of both sugar and rhubarb is used.

Rhubarb Marmalade.

This is good and may be used in many ways in winter. Use three-fourths as much sugar as you have rhubarb by weight. Cut the rhubarb in one-inch pieces; add sugar and let stand over night. In the morning, place in a granite pan and cook slowly for one hour; stir frequently. After it has cooked for about three-quarters of an hour, add to each quart of fruit the juice and rind of one lemon.

Rhubarb Cream Pie.

One cup of rhubarb chopped fine; one cup of sugar, one-eighth of a teaspoon of salt, grating of nutmeg and a little grated lemon peel. Moisten one tablespoonful of corn starch with a little cold milk; beat until smooth; then add one cup of rich milk or cream, and add to mixture of rhubarb and sugar. The cream or milk should be made hot enough to partially cook the corn starch so that it will not settle to the bottom of the pie, which will make it leathery and not acceptable. This filling can be cooked and placed in the baked pie crust, or it may be placed in the unbaked crust and cooked therein. It may be put between two crusts or put in one and covered with meringue. The yolks of two or three eggs may be added, by way of variation, if desired.—Lotta I. Crawford. In Bulletin of Colorado Agr. College.

Rhubarb Meringue Pie.

While rhubarb pies are usually cooked with two crusts, some very nice ones may be made with only one crust. The same mixtures may be used to make tarts or tiny pies for the children's lunches. Many who do not care for plain rhubarb are delighted with it when used with other fruit. The idea of upper crustless pies is largely to get as much fruit as possible with little paste, and yet have pies and not sauce.

Stew together 2 cups rhubarb, 2 cups sugar, ½ cup water. When soft, add beaten yolks of 2 eggs and press through sieve. Bake without top crust. When done, beat whites 2 eggs to a stiff froth with 1 tablespoon powdered sugar, spread on top and bake until brown. Serve cold.

Rhubarb Custard Pie.

Stew two cups of rhubarb, press through sieve or beat until smooth. Add one cup sugar, 1 egg, 1 tablespoon cornstarch, butter size large nutmeg. Stew together a minute. No upper crust. Add more sugar if desired very sweet.

Rhubarb Apple Pie.

Two cups of stewed rhubarb, 1 cup sugar, teaspoon butter, teaspoon flour, 1 cup apple sauce. No upper crust. If preferred, however, a crust can be put on, but it is nice without. Here is another: Cook 6 apples until smooth. Add 1 cup of sugar, 1 tablespoon lemon juice, 1 tablespoon cornstarch and 1 cup stewed rhubarb. With or without upper crust.

Rhubarb Prune Pie.

One cup stewed rhubarb, 1 cup sugar, one cup stoned, chopped, cooked prunes., Boil together for a few moments. Sprinkle a little more sugar on top of mixture after bottom crust is filled. Cover and bake.

Rhubarb Pudding.

Sift together 2 cups flour, pinch salt, 2 teaspoons baking powder, ½ cup sugar. Stir in 1 egg beaten with ½ cup milk, or cream, and 2 tablespoons butter. Add 2 cups rhubarb cut into small bits. The pink part with the skin left on is the nicest for this pudding. Boil in floured cloth until done and serve hot with any sauce.—[S. C. P., Massachusetts.

WITH A SEIVERT OIL BURNER

You can burn 100,000 feet of air with every 130 gallons of oil; this means perfect combustion. To burn more than 100,000 cubic feet of air with 130 gallons of oil, there is a decided loss of heat. To burn less than 100,000 cubic feet of air there is a loss of fuel. The only safe and reliable burner on the market. Send for full particulars.

SIEVERT OIL BURNER CO. 1001 No. Alameda St., Cor. Main and Ord Sts., Los Angeles, Cal.

Citrus Market

LOS ANGELES, May 22, 1907.

The weakening market reported last week has disappeared and a stronger tone now prevails in oranges. The slightly lowered prices of last week caused an increased consumption and the better tone soon prevailed. Navels have been cleaned up in some packing houses so that the few now remaining will find a cleaner market.

Valencies are finding fair treatment. The valencies shipped to date are from north Tehachepi. From that section there wil be about one hundred cars. Shipping from Southern Californi points will aggregate about 2000 cars and will not be forwarded in quanitit for some weeks.

Lemons indicate a better tone than last week. There is still a large qauntity of foreigns on the New York docks, but it is being worked in to the market gradually, and the superior quality of California lemons gives them certain advantage.

Yesterdays sale opened steady and maintained a good tone.

Shipments average 150 to 200 cars per day and, to date, aggregate 19920, of which 1884 were lemons. Same date last year 20,271, of which 2,179 were lemons.

NEW YORK, May 20,—There is a good active demand and prices are generally higher on all sizes and grades. Weather partly cloudy. Thirty-eight carloads of oranges and one carload of lemons sold.

Frank E. Kellogg, of Goleta, has sold his fifty-six acre walnut orchard to J. F. More for the magnificent sum of $1000 per acre. This place cost Mr. Kellogg $150 per acre thirty years ago.

The Ventura Press reports that canneries are offering as high as $70 per ton for apricots. If this is the case, there will be no dried 'cots this season.

O. L. Miller, of Lafayette, Colorado, recently purchased the Anderson orange grove at San Fernando.

For a good, Practical Milking Machine see the O. J. Weber Co., 555-557 S. Los Angeles street, Los Angeles.

ANOTHER FINE JERSEY.

Guy H. Miller, formerly of Riverside and now located at French Camp, near Stockton, with his Venadera herd of Jerseys, writes us: "It may be of interest to your readers to know that another California Jersey has made an excellent official yearly record. Signora Bruce a cow of my own breeding, a short time ago finished a yearly test under rules of the American Jersey Cattle Club for authenticated fat tests. I have just received word from the Club that the test has been found correct and with her score 87½ points, admits the cow to entry in Class A of Register of Merit.

For the 365 days Signora Bruce gave 8686 lbs. of milk, containing 487 lbs. of fat, equal to 573 lbs. of butter 85 per cent. fat. She was fed during the year 1282 lbs. of ground barley, 282 lbs, of caproco meal, alfalfa hay night and morning. She is an orange fawn in color with a little white, weight about 1000 lbs. Since finishing the test she has again freshened, dropping a nice heifer calf, her third heifer. She has had two bulls; the oldest is now in the herd of J. M. Huston at Imperial; the other I presented to the California Polytechnic School at San Luis Obispo. These sons of so good a dam should prove valuable sires in the hands of their respective owners."

Mr. Miller breeds fine Jerseys and is worthy the success which will come from conscientious work.

CHICO NURSERY SOLD.

A sale has been consummated whereby F. W. Power, who has held the controlling interest in the Chico Nuresry Company, and M. McDonald and A. McGill, minority stockholders, have disposed of their entire interests in this company to F. X. Bouillard, E. Wightman and E. Harlan, of this city, who are now sole proprietors.

During the time that the company has been under the present management, Mr. Wightman has been the head office man, and whenever Mr. Power was absent had entire charge of the office, and Mr. Harlan was assistant foreman, so that all members are perfectly familiar with the business and no change will be made in the policies of the company.

During the time that the Chico Nursery has been under the management of Mesers. Power and Bouillard, it has grown from a small affair until now it is one of the largest in the State, spending at Chico alone, for labor and necessary supplies, between $40,000 and $50,000 per annum. The past year has been the most successful in its business, and sales, they say, would have been much larger had they not sold so nearly out of trees shortly after the first of the year and long before the end of the planting season.—Chico Record.

UNDERSTAND YOUR SOIL.

The plowing and tilling of the soil is not alone for weed destruction. It plays an important part in maintaining a physical condition suitable for plant development.

It is impossible for an agricultural paper to tell any farmer just what is best to do in his particular case. Nor is it best to rely on the experiences of farmers who may speak on these subjects at farmers' institutes, for the reason that in some States there are many kinds of soils and climates. What is good for one soil may be detrimental to another. One farmer may get up and say that he never had good success with deep plowing. Why this lack of uniformity of experience in one country? Because each may be farming a very different class of soil and each tell the truth as he has found it.

In some things it is best to make some local experiments. State experiment stations can solve certain problems and make certain deductions, but each farmer must know whether or not they will fit his case.

A writer may advocate sub-soiling and tell of its great benefits. The reader must consider the locality in which the writer lives. He must know the nature of the soil in that locality before he sits down to write a contradictory article or says to himself, "That's a city chap, who doesn't know what he is talking about." Nor would it be safe for him to say, "Well, if that's his experience, I'll try it too." Sub-soiling proves of benefit where the rainfall is scant and the surface pact nature and the rainfall is scant and the surface or sub-surafce is light, sub-soiling is not beneficial, but harmful.

The same differences govern the question of spring and fall plowing, of deep and shallow cultivation, of planting by the usual method or listing. It is well to find out what is best for average years on a given farm and then take some chances on the weather. By doing part of the work one way and part another we can soon learn which is best, or equalize the chances of partial failure in certain operations such as plowing.

SEEKING PARDON.

The friends of E. B. Thomas, at one time Forest Supervisor of Southern California, are petitioning President Roosevelt for his pardon. Mr. Thomas was convicted of falsifying his books to defraud the government and fined $7000 and given a term in the penitentiary where he now is. His guilt seems to be unquestioned, but many think the punishment unduly severe. One of his friends says:

"We have based our case entirely upon the need of Mr. Thomas' family." "The fine of $7000 swept away all of the man's property and left the wife, little girl and mother without means. Mr. Thomas' aged mother does not know that her son is in the penitentiary."

Eight hundred acres of the Hollenbeck ranch, southeast of Azusa, have recently been transferred by Leonard Merril to Hon. J. W. Riggins, recently of Waco, Texas, for $60,000. Extensive improvements are promised.

The Talbert drainage district is to be increased by 500 additional acres at its northeast corner.

Tulare County's Citrus Fruits

SOME of Tulare county's claims as a citrus producing section have been looked upon as slightly tinged with "hot air," but to the observing visitor who takes a look at the well-kept groves and the extent of them, there is a realization of the worth of that community, and of the fact that the reasonable claims of its warmest friends will be made good. In fact, are being made good for by the views on this page, may be seen some scenes in the neighborhood of Lindsay which show a scope of orange planting truly astonishing. The illustration of the exhibit of Lindsay at Tulare County Citrus Fair held at Porterville last December, shows that Lindsay not only grows quantity, but has an artistic taste in displaying her principal product. The next Citrus Fair will be held at Lindsay next December, and it goes without saying that artistic displays of fine fruit will be made. Water is near at hand and its securing has not caused great outlay, so that further development of this fine section

along citrus lines may be expected. Nor is the citrus the only product, for the visitor at the last fair found while the orange predominated, as was eminently proper at such an occasion, there were also deciduous fruits, grains and many other farm products, not the least of which were some remarkably fine specimens of dairy and other stock.

Regarding the orange in Tulare county it is claimed there are over 10,000 acres now planted in citrus fruits, nearly all of which have been planted since 1888, though the very first experimental plantings were made as early as 1880 at Porterville and Lemon Cove. Since then there has never been a serious setback on account of unfavorable weather conditions. In fact, the high summer temperature tends to ripen the fruit much earlier than other citrus sections, so the fruit is usually all off the trees and marketed before the Christmas holidays. If it is desired to hold over the late oranges, as has been done with over a hundred cars of Valencias this year, it goes through the season in good condition.

Sugar Beets in the San Joaquin

The Successful Factory of the Pacific Refining Company at Visalia Affords an Outlet for 4000 Acres of Tulare County's Products.

BUT a few years since it was claimed that the great San Joaquin Valley was not adapted to sugar beet culture. A little later a few "wondered" if the conclusion were correct. Then a few hard-headed, "show me" men said we'll know to a certainty. Indifferent success or occasional failure meet the first experiments, but nothing daunted, the matter was followed to a successful conclusion and we now note the following item in the Visalia Daily Times:

One Hundred and Fifty Men at Work.

"Another industry, and one of the most important, is the beet sugar factory established last year and operated during the summer for the first time. This industry is a new one in the San Joaquin Valley but has proven most successful, so much so that the acreage planted this year is increased one-third over last—from 3000 to 4000 acres. From this vast area it is expected that 40,000 tons of sugar beets will be raised, which means about 4000 tons of pure sugar of an approximate value of $400,000. During the operating season 150 men and boys find employment at the factory."

The institution which makes four hundred thousand dollars to grow where one blade of grass grew before, is certainly accomplishing results for those farmers who receive the benefits, worthy of note. This institution is the property of the Pacific Sugar Company and is the only one in the great San Joaquin Valley. It is to be hoped that its success will be such that other factories will spring up all over the great valley.

The factory, situated one mile south of Visalia, was completed last year and represents an investment of a half million dollars. It has demonstrated by actual experiments the adaptability of the soil of that section for the successful and profitable culture of sugar beets. It has a capacity of 350 tons daily and employs a large working force continuously.

Four thousand acres are now planted to sugar beets for the campaign of 1907 and from $250,000 to $300,000 will be paid to the farmers for the crop. In many instances the return from the crop will be equal, if not greater, than the present price of the land upon which the same is being grown.

Wonderful Development.

The beet sugar industry has developed wonderfully during the past few years, but in view of the fact that the increase of the consumption of sugar nearly equals the increase of production and that the United States imports more than 70 per cent. of the sugar consumed—there would seem to be no doubt as to the advisability of acquiring land that will produce sugar beets and of becoming proficient in the science of cultivating them. In all sections where factories have been established, land has increased from 200 to 300 per cent. in value and there is no section of the United States that is better adapted for this industry than Tulare county, California.

The sugar beet is a product which requires intense cultivation, hence, gives larger returns to the farmer who will meet its requirements. That the great interior valley has been proved by this enterprising company, to be well adapted to beet culture, gives much gratification to every well wisher of the State. Hence, a word as to the method of culture which has proved successful in that section, written by one thoroughly conversant with the subject:

How to Grow Sugar Beets.

Now on October first I would look up and contract with some one to plow and subsoil my land for me. The ground to be turned over two inches more than before, say seven or eight inches, and in addition subsoil every furrow to an additional depth of seven or eight inches; thus stirring the ground to at least a depth of fifteen inches. There are three ways employed in this kind of plowing:

(1.) Plowing with a 14-inch plow, two horses, and following with a regular subsoil plow with two horses; (2.) Plowing with a single 12-inch plow with subsoiler attached and three horses; (3.) Plowing with a 14-inch disk plow with subsoiler attached and four horses. The first costs the most but it is better in the end. Let us suppose that it has taken twenty days to do this plowing. I would contract to have some one harrow the field, heavy. It would be a good plan to harrow the field after each day's plowing. Then I would allow the field to stand until rain came, at least one inch. If this occured any time before December first I would give the entire field a light harrowing ,in fact, would not allow a crust to form at any time. Now suppose the first of January arrived and we had one to three inches of rain; I should again contract for a party to go on the land with a team and disk up, harrow, roll or clod mash and cross harrow ten acres of this land the first week. Having now a good seed bed and finding the surface and bottom moisture united, and the top moisture not over one-half inch from the surface I would hire a man and team to do the seeding at a stated price per acre. The seeder would be set so that the rows would be eighteen inches apart and the seed desposited three-quarters to one and a quarter inches below the surface of the ground, depending upon the amount of moisture present. As the seeder plants four rows, I would have the marker so placed that I would leave an extra space of six inches between every fourth row. If I found upon finishing my seed bed that the top moisture was more than three-quarters of an inch from the surface I would roll before seeding, with a rough corrugated iron roller. The first ten acres are now planted and while we are waiting for the germination and appearance of the plant, which usually takes from ten to fourteen days, we proceed with planting the next ten acres, repeating the process described. Should a heavy packing rain come before the seed is up on the first ten acres I would go over with a light harrow, with the teeth turned backward so as to break any crust that would interfere with the growth of the young plant, but not so deep as to disturb seed. Suppose now that the seed is all up, and it was not necessary to break the crust in the manner mentioned by light harrowing, and the young beet shows two to four leaves, I sould have my labor contractor on the ground, ready to do the thinning and just before he commenced I would roll the ground with a light smooth roller and immediately follow with a cultivator, The purpose in rolling is to make the rows of beets stand up prominently, to facilitate the cultivating. The contractor then sets his men to work the first man uses a hoe and blocks off the beets leaving bunches of from two to six beets every seven to nine inches. Immediately following this man, comes another who takes two rows at a time, and who pulls all the beets except the strongest in the bunch, and at the same time tucks about the root of the beet a little loose earth. Three men will do from one-half to an acre per day, the amount depending upon the weeds state of the tilth and other local conditions.

Deciduous Fruit Culture

By J. W. MILLS

HARVESTING ALMONDS.

ALMONDS should not be gathered till the husk will separate from the nut without leaving the hull white or uncured in spots. Premature picking will make a bad looking nut on this account, and it makes the handling more expensive because the husks stick. When the husk will separate freely it is time to gather them. There will always be some nuts on which the husks will stick. This is usually due to some disease of the nut and is almost always due to gum.

Sheets made of burlap and big enough to cover all the surface under the spread of the top when one strip is placed on each side and lapped, make the most economical sheets for picking. The nuts are knocked off with slender willow or bamboo poles. If the trees are large and tall, a man in the top with a short pole will do more work than two with large poles on the ground. He can employ quicker action. The nuts are gathered up in picking boxes and taken to the hulling shed and run through the hulling machine at once. If this work is delayed the husks will become dry and cling to the nuts, necessitating much hand work. The nuts are piled on a table around which men or women are seated and the nuts sorted out and put in boxes. It will not do to pile up or put in picking boxes right from the huller but allow them to stand a couple of days as there will be enough green husks to cause heating and a discoloration of the shells in places. Each person at the table should have a piece of wood, a dry branch will do, about 10 inches long and an inch and a half thick, to break open "sticktights," nuts on which the hulls stick and throw the kernels there obtained into a small box conveniently placed within reach of two operators.

These kernels should be separated into broken and wholes. Both classes have a good sale and the whole kernels sometimes bring as high as 35 cents, or more, a pound.

There are a few locations in California where the quality of the almond is superb. It makes a bright, attractive nut that cannot be improved upon in appearance by bleaching. These areas are quite limited and as far as developed are not very productive. The requirements for such development in quality are supplied entirely by climatic conditions. These conditions are not conducive to the development of heavy crops, so that what is gained in one way is lost in another.

The locations which produce large crops, produce nuts that are liable to have dark shells and it is this quality that the growers are required by the trade to improve. The only method is to bleach them. This is done by the use of sulphur fumes or a solution in which the nuts are dipped. Neither of these two methods will affect a hard shell almond, but the soft and paper shells are more or less injured by having the flavor destroyed. Paper shell almonds have openings in the shells that admit the bleaching fluid and sulphur fumes which destroy the flavor at once and in a short time the nuts become rancid.

Bleaching with sulphur is done by placing the nuts in a bin with a perforated bottom, sprinkled slightly and sulphured from below so that the fumes will pass through the perforated bottom and on up through the nuts. After leaving the nuts in this bin for four or five hours, they are spread out to dry or put in shallow boxes, then sacked for market.

Nuts that are to be kept for use should never be bleached. Place them in shallow boxes till thoroughly dry and put away in sacks.

OLDEST ORCHARD IN AMERCIA.

The oldest apple orchard in America, if not in the world, is in the center of the ancient town of Manzano, eighteen miles southwest of Estancia, Terrance county, New Mexico. Many of the trees are more than six feet in circumference, but all are still fruitful and vigorous, although neglected for generations. Little is known of the history of this orchard, but the oldest inhabitants of the valley of the Rio Grande remember the orchard from childhood, and say that the trees have not changed in appearance since then. Venerable Mexicans and Pueblo Indians tell of visiting the orchard as far back as they can remember and finding apples on the ground in all stages of decomposition at least two feet deep.

The Estancia Valley has been peopled for ages, probably by the kinsmen of the natives found by the Spanish explorers at Gran Quivira, Abo and other ancient cities. Probably in the early days of the Spanish occupation some Franciscan monk found his way to Manzano, and there planted the seeds that have developed into these venerable trees. They are, no doubt fully three hundred years old.

Close by the orchard is a little lake, fed by a large spring. A short distance away is a grove of pines and cedars, making an ideal place for picnic and camping parties.—The World.

CALIFORNIA GYPSUM.

There are now four gypsum mills in the State, one at Amboy, one at Los Angeles, and two at Palmdale. Of those at Palmdale one is still in process of construction. The product of these mills is consumed in the State. It is used mostly for wall plaster, but a smaller amount is ground for fertilizer. Generally speaking, the gypsum runs from 54 to 90 per cent. pure. Deposits occur, however, in the form of alabaster, which are very pure and are suitable for the manufacture of plaster of Paris, but they are far from railroads, and so at present unavailable. Gypsum sets very quickly, usually in about five minutes. Because of this, a retarder, often consisting of slaughter-house refuse, dried and powdered, which delays the setting from fifty minutes to two hours, is employed. There is nothing peculiar about the California gypsum, as distinguished from that of other localities, except the fact that perhaps at one of the plants it is necessary to regrind the gypsum after calcining it. —[San José Mercury.

Foreman (after ten hours of it)—But why—why—in the face of such evidence in his favor, do you still believe the man to be guilty?
The calm minority—Why? Oh, because!—Puck.

Mrs. Backpay—Good morning, sir. Will you take a chair?
Installment House Collector.—No, thank you, ma'am. I've come to take the piano.—Philadelphia Record.

UNIVERSITY FARM SHORT COURSE.

The State University is sending out a circular on the scope and aim of the new University Farm near Davisville, from which we quote:

The University Farm, the selection and purchase of which was provided for by an act of the California Legislature of 1905, consists of about 780 acres of first-class valley land contiguous to the town of Davisville, in Yolo county. The farm is upon the irrigation system of the Yolo Consolidated Water Company and water rights covering the whole acreage accrued to the University by donation from the citizens of the vicinity. The farm is very eligibly situated at the junction of the Oregon and Central overland railway routes, at a distance of thirteen miles from the city of Sacramento.

Character of Instruction on the University Farm.

The purposes of the University Farm and the duties of the Regents of the University in connection therewith are defined by the statute as follows: "The Regents of the University shall appoint the necessary instructors and inaugurate and provide for the conduct of instruction in agriculture, and in such other branches of learning as are allied thereto, and as are caculated to better qualify and inform the students attending in the theory and practice of agriculture. This instruction shall be conducted in connection with, and as a part of, the College of Agriculture of the University of California, provisions being made by the Regents for such attendance on the farm of the college students as may be deemed best and necessary to the completion of their college courses. The University Farm and the instruction thereon shall be so conducted as to meet the needs of persons who desire instruction in agriculture, horticulture, viticulture, animal industry, dairying, irrigation and poultry raising, and to prepare them for the pursuit thereof; and shall be used for experimental and investigational work in connection with the agricultural experiment station of the University of California. Short courses of instruction shall also be arranged for in each of the leading branches of agricultural industry, so regulated as to provide for popular attendance and general instruction in agricultural practice."

* * * *

Immediately upon the attainment of title to the tract of land at Davisville the Regents of the University entered upon the construction of buildings and purchase of equipment so far as the balance of the appropriation remaining after payments for the land, made by the commission empowered by the statute for its selection and purchase, would provide them. Building is now in progress upon a capacious creamery to furnish ample accommodation and equipment for manufacture of butter and cheese and by-products on a commercial scale, with additional rooms for lecture and laboratory instruction. There is also in construction a livestock pavilion arranged to illustrate instruction by direct use of animals and to serve as a lecture-room for large classes in other subjects, and as a general auditorium. Contracts have also been let for the building of cottages for instructors and foremen. Appropriations by the Legislature of 1907 will provide dormitory accommodations for students, barns and sheds for stock, simple buildings for horticultural, viticultural, and other instruction, shops for farm me-

chanics, sheds for tools, implements, etc.

The first offering of instruction in Agriculture on the University Farm will consist of a series of short courses calculated to meet the demand for knowledge of particular branches of California farming, and at the same time to connect these short courses so that one electing to pursue them consecutively could obtain a general insight into all of the most prominent lines of agricultural effort in this state and be aided in choosing from them the directions of his own undertakings.

The short courses this year are:

Dairy School.—Oct. 2 to Nov. 26.

Animal Industry and Veterinary Science.—Oct. 30 to Nov. 26.

Cereal Culture.—Nov. 6 to Nov. 26.

Irrigation and General Agricultural.—Dec. 3 to Dec. 21.

Wine Making and Wine Testing.—Jan. 2 to Jan. 8.—

Grape Growing.—Jan. 9 to Jan 15.

Orchard Practice and Protection.—Jan. 16 to Feb. 5.

Full information may be had by addressing Acting-Director Wickson at Berkeley.

TEA GROWING IN CALIFORNIA.

We notice new efforts are being made to grow tea in our State and, so far as the growth of the plant is concerned, it will unquestionably be successful. We have known of tea plants growing here from our earliest recollection, as we have of tobacco, but in neither case has commercial success been achieved, for several reasons. In the case of tobacco there is reason to expect that suitable soil and conditions will yet be discovered to make its production a commercial success, but this is doubtful in regard to tea. The tea plant belongs to the camellia family, and requires largely the same conditions and treatment, but the tea of commerce is a manufactured article, and in its manipulation requires great care, combined with expert knowledge, and exceedingly low wages, none of which, especially the latter, can be had in California. Tea growing for curiosity is all right, but as a commercial proposition, it is as well let alone.

GUARD AGAINST BORERS.

Newly planted trees should be carefully guarded against borers. Now is the season when the females are laying their eggs on the young trees and these, as soon as hatched, will commence to burrow their way into the trunks and, once inside, the damage is done and the tree permanently injured. All young trees should be carefully shaded from the direct rays of the sun. A piece of old gunny sack wrapped around the stem will answer, or any of the tree protectors made for the purpose are excellent. If left exposed there is always danger. The protection should remain until the tree has produced a sufficiently large top to protect its own trunk, when there will be little danger.

WRITE LETTERS.

The work of every commercial organization throughout California is devoted to increasing population by bringing in a desirable class of immigrants, and to this end The California Promotion Committee has urged that material assistance can be given by the people of a community if they will constitute themselves into individual committees on population, by writing letters to their friends and relatives in their old homes. If every farmer in California who has come here from some other country or some other State will write letters back to his old home, and will also send names in to The California Promotion committee, San Francisco, he will be doing big work toward building up the State, and especially in bringing in men and women who will solve the industrial question of sufficient labor supply for the agricultural districts.

The committee will write to all people whose names are sent in, and in doing so will tell at whose instigation they are writing.

TRANSPLANTING "BIG TREE" SEEDLINGS.

Contrary to prevalent belief, the famous "Big Trees" of California do reproduce themselves under certain favorable conditions. The trees seed freely, but the seed rarely germinate except when they fall where the ground has recently been burned over. Once started the young growth only needs a moderate amount of light and protection from fire and stock grazing. With some care this race of forest monarchs need not become extinct, but may be greatly multiplied. The number of mature trees is not great, and healthy young growth is rare, but in some situations there are plenty of seedlings. In order to establish these trees more widely, it is proposed to move some of the seedlings to localities where they will be apt to grow.

OVERWORK A WASTE OF TIME.

Overstrained faculties can never bring out the best results. Overwork is always a waste of time; and though it may not seem to be so at first, eventually the sad truth is always manifested. To cut off needed recreation, to curtail the hours of sleep, to postpone a holiday indefinitely, to refuse to take rest and ease and change, under the impression that thus time is saved, is always a short-sighted policy and often a fatal mistake. The time arrives when the poor, abused faculties take their revenge and refuse to serve altogether, or do in so feeble a fashion as to show their deterioration.

MAY MOVE.

The Crayton Manufacturing Comepany are considering moving their factory away from Long Beach, as they have had strong inducements from several other towns. They manufacture the Perfection Acetylene Generator, one of the best generators on the market today.

The Chamber of Commerce of Long Beach made a thorough examination of this concern, and their report is as follows:

"Your committee, to whom was referred to the question as to the merits of the Perfection Acetylene Generator, manufactured in this city by the Crayton Manufacturing Company, beg to report as follows:

" 'We have taken the trouble to inquire of parties who have had in use for a number of years the acetylene generator manufactured by this company, and we find that in every case it gives excellent satisfaction. So far as we can find, those who use this generator are unqualified in its praise, especially emphasizing the quality of light it furnishes.

As the Crayton Manufacturing Company are not asking anything in the way of land or bonus to carry on their business, your committee feels warranted in saying that the enterprise is one likely to contribute materially to the growth of the city, and as such should be commended.

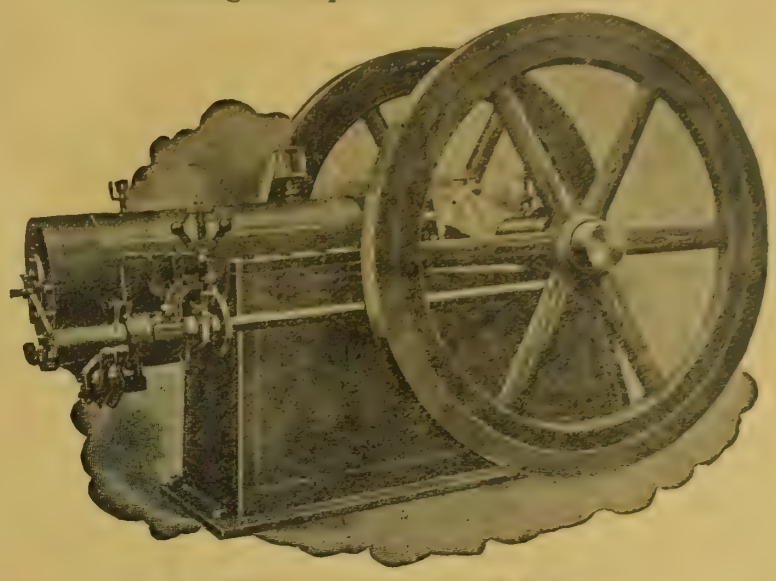
The factory is one that will employ at least fifty men in the coming year, and will be a credit to the town where they may locate.

Columbus Engines

MADE BY

Columbus Machine Co., Columbus, Ohio

Have stood the test sixteen years.
The largest output in the United States



Standard Horizontal, 4 to 60 H. P.

Read what this man says about Columbus Engines:

Greenleaf-Compton Company, Tropico, Cal., 4-3-07.
121 So. Los Angeles St., Los Angeles, Cal.

Gentlemen—For about four years, I have used a Columbus engine of ten (10) horse power; which has been running a 3½ Vertical pump and pumping about 35 inches water with a 90 foot lift, and when the time came to buy a new pumping plant for my ranch near Anaheim where we we shall need water for about 200 acres, I decided to have a 60-horse Columbus engine installed, and placed the order with you because I expect to have a pumping plant that cannot be excelled.

Respectfully, E. B. BARY.

This 10-horse engine is pulling 13½ horse power. We are installing a 60-horse plant for Mr. Bary, 3½ miles north of Anaheim. Come in and let us demonstrate the simplicity of Columbus Engines.

FORWARD QUESTIONS DIRECT.

We desire to call the attention of the Cultivator readers to the fact that they should mail this office direct any questions they desire answered on poultry, stock, dairy, horticulture, or agriculture. Do not write to individual members of the staff but send all questions direct to the office and they will be answered by the editor having charge of that special department.

GROWTH OF THE CULTIVATOR.

The California Cultivator has reached the respectable circulation figure of 12,000 subscribers. No other weekly agricultural or horticultural journal in the state, nor on the Pacific Coast surpasses the Cultivator in its field of information. The very best talent is employed on its staff of contributors and the statements made by these expert writers may be relied on as practical to California conditions.

It is the aim of the Cultivator to keep in the forefront in the agricultural and horticultural field and to give each week the most valuable information to be gained along these lines.

Correspondence, questions and suggestions are specially invited and will always receive prompt and careful attention. These questions and suggestions should be sent direct to the Cultivator office and not to the staff contributors. Bear this instruction in mind to insure prompt attention.

The slump in the New York stock market last month as predicted had no serious effect on the general conditions of the money market. The gamblers on Wall street suffered, but nobody cares especially for them. The country at large is the most prosperous in its history, owing largely to the agricultural greatness of the past decade. So long as the farmer prospers the country will experience no serious backset.

THE VETERANS' DAY.

May 30th is distinctly the Veterans' day. It has been set apart to commemorate by fitting tribute, the services rendered the Nation by the living and dead heroes of 61-65.

It is purely American in its observance; no other nation has such a day, nor do such thrilling memories cluster around any given period of time. It is both right and proper that the observance of the day should be marked by a spirit of unostentation; that with songs and flowers and tributes we should decorate the graves of our Nation's defenders as becomes a people chastened by the reverses, the loss of human life, the expenditure of treasure, which the war of the rebellion evoked.

It is also befitting our great National Christianity that we should put away all thought of malice or hatred, toward those who caused this fearful sacrifice, and standing by the green mounds of our soldier dead, both North and South, pledge our faith and love anew to the righteous principles upon which this government was founded.

Let the past be forgiven—if not forgotten—and let us bind ourselves once again in a common bond of brotherly love and national unity, swearing eternal fealty to the flag, the constitution, and the indissoluble union of the States. Let us pledge ourselves anew to defend the honor of the Republic against the heresies of anarchists, or the preaching of the enemies of good government. Our comrades died that this government might live. Let us maintain to the end the principles for which they sacrificed their lives.

CELERY GROWERS FILE CLAIMS.

The celery growers of Orange County, who claim to have lost $150,000 through the failure of the railroad to move their crops, contemplate bringing suit to recover damages therefor. The Interstate Commerce Commission, which was to have meet in Los Angeles last week, would have taken up this matter and gone to the bottom of it with a view to ascertaining why the railroad did not furnish cars to move this crop.

It has been contended by the railroads right along, that it did not have cars sufficient to move the California product, neither in the North nor in the South. To determine the question from an official standpoint, the Interstate Commerce Commission would doubtless have summoned the managers of the railroads in question; namely, the Southern Pacific, and Santa Fe, and their answer would have been a matter of record.

The California Vegetable Union, acting for these celery growers, will file, it is said, if it has not done so, claims with the Southern Pacific officials for the amount demanded, but it is stated that this will be the end of its action as it does not intend to take steps to recover remunerative damages.

The shippers' aim is to avoid legal complications by showing the railroad company, in a friendly manner, just how they lost their crops through its failure to furnish cars when the same were most needed.

It is claimed such a failure, when the shortage was most felt, the California Vegetable Union officials investigated and found large numbers of empty cars scattered along the line of the roads. These were furnished when the demand became strenuous, but never in sufficient numbers to move the crop, and immense quantities of the finest celery was left to rot in the fields. To recover the loss, it is claimed the railroad company is responsible for, a suit at law is now threatened. With the present temper of the people, on the matter of car shortage, it seems to us that the railroad company should give the subject most careful attention to the end, that the losses which occured by reason of failure to supply cars in adequate quantities to remove the crops may not be repeated.

DOLLAR WHEAT.

The spectacle of dollar wheat on the Chicago market reminds one of the days of '67 when the country went wild for a time, over the phenomenal wheat market which reached $2.50. The craze on 'change then started much as the present one has, because of apparent shortage in the wheat producing sections of the world, with our own peculiar climatic conditions which made the outlook for the crop anything but promising. Of course, the market did not remain at the $2.50 point very long, but, however, sufficiently long to permit Armour, "Old Hutch," and several other operators on 'change, to rake in several millions' personal profit. From a purely commercial view there is no reason why wheat should soar above the present market quotations. Wheat at $1.00 is not excessive as compared to prices charged for other necessities of life, and growers will be correspondingly benefited by the rise.

It will probably be found later, that the present boom is a grain-market job engineered by individuals to make a big profit out of apparently adverse conditions. The rapidity of the jump in price leads to that conviction at least.

Here are some of the high prices reached by wheat during "corners" and scares in the past years when the dollar mark was exceeded: 1867, shortage in crop, $2.95; 1888, cornered by "Old Hutch," $2.00; 1898, cornered by Joe Leiter, $1.85; 1904, "black rust" scare, $1.24.

We are glad, however, to know that growers will realize good results for wheat as $1.00 per bushel yields the producer a handsome return. There is one thing about all these high prices for farm products, the man who is behind the plow gets his share of whatever advance there may be, sooner or later.

SUGAR BEET.

Continued from first Page

The contractor should have enough men to do the ten acres in one week, as it is much better to thin while the beets show from two to four leaves than to do so later. By thinning at the proper time, the increase in yield will be ten to twenty per cent. higher. If a rain does not come before two weeks after thinning I would cultivate, and should continue to cultivate every two weeks. By the middle of March I should be able to judge from the amount of previous rainfall and the state of moisture present in the soil as to the advisability of irrigating, also by this time the leaves would be so large that it would hardly be possible to cultivate further. So then plow between every fourth row as clean a furrow as possible and run the water down the furrow by simply opening the head ditch and allowing the water to flow to the end of the furrow. One man should irrigate at least five acres per day enough water to give the ground a good soaking, and the plowing for the ditch and cultivating can be done by a man and light team. I should use enough so that the land would be wet from one ditch to the other, this under ordinary circumstances will occur by the time the water has reached the end of the furrow. Then turn into another furrow, and so on until the whole ten acres has been so treated. Then just as soon as I could get a cultivator at work, I would give a deep cultivating for the last time, and have the contractor hoe out all the weeds. After this there is nothing to do until harvest time, which will arrive some time in July or August. Upon being notified by the factory to deliver beets, I would instruct the contractor to commence plowing out on a certain day, and to have the help on hand. I should then use a single subsoiler with a special share extending on one side only and plow down beside every row of beets at a depth of about fourteen to sixteen inches, so as to loosen the beets in the rows. The contractor could then put his men to pulling the beets up, at the same time topping properly and throwing them into piles. When a pile is finished it should be covered with leaves. Prior to this time I would have contracted with the same party to do my hauling, the loading is part of the labor contractor's agreement. I should try to harvest about as many beets per day for the factory as could be plowed out by one team in three-quarters of a day. In case the plowing proceeded faster than the topping and hauling, the plow team could be used for hauling, simply keeping enough beets loosened ahead. When all the beets were in and as soon as I collected from the sugar company I would settle with my labor contractor. I would sell my pasturage at $1.00 to $2.00 per acre, insisting that the feeding be done on the premises and that the cattle be taken out in case of rain. As one-third of the mature beets are tops, the feed left on an acre would be, even after drying out, at least two tons of tops and crown, which will be very valuable at this price. Then as soon as the feed is off, I would begin to prepare for next season's crop.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Fullerton is moving for better roads.

Glendora boasts of a total rainfall of 32.62 inches.

Work has begun on a boulevard connecting Riverside with Redlands.

The Inter-urban Electric R. R. will connect Glendora with Los Angeles by August first.

Farmers of Imperial Valley are talking of planting large quantities of wheat next year.

The Santa Ana Bulletin says that the output of olives this year will be very satisfactory.

The beets about Santa Paula and Saticoy section are reported in the best of condition.

A ten-acre farm at Imperial sold recently for $1500, which is $150 per acre for "desert" land.

The grain about Rialto needs rain. In some places the nelds are infested with a small green bug.

The Santa Fé Railroad Company has purchased the San Diaguite ranch for the planting of eucalypts.

Coachella cucumber crop is moving to market; a thousand crates will be shipped within the next two weeks.

The mountain road, crossing the mountains north of Glendora to the San Gabriel River, is to be begun at once.

The Santa Paula Chronicle says that these are busy days with bean planting, hay making and beet cultivating.

Geo. H. Waters of the Pomona cannery is greatly improving his cannery, preparing for the increased output this season.

Bee keepers in from the hills occasionally report great quantities of bloom and bees making honey for an immense crop.

Pieces of decayed wood were brought up from the bottom of a 385-foot well being driven in the vicinity of San Bernardino.

Imperial farmers will plant corn this year during the month of August, claiming they get better results than in the earlier season.

A new variety of sorghum is being distributed by the government in the neighborhood of Yuma; also new varieties of orange seed.

Chino hay growers have raised the price of alfalfa to $10 in the field. This is claimed to be because of the loss from army worms.

New water developments are being made in the Antelope Valley. It is predicted by the Ledger that larger developments will follow.

The Claremont Horticultural Club met at the home of Mr. W. H. Howell, at Lemon, recently, having most helpful discussions on fruit raising topics.

The Imperial Valley Standard reports the consuming of water for irrigation is much less than formerly, owing to the maturing of the hay and grain crops.

On account of the disaster caused by the New River inroads to the town of Calexico, the business section of that little international town has been materially changed.

A Redlands horse man insists there is money in horses, having recently extracted a five-cent piece from under the skin of a horse which had a bad looking bunch on its leg.

The opening of the government land in the Yucaipe Valley is attracting much attention from farmers; dairymen in particular having their eye on the rich lands of that valley.

The owners of a fine German coach stallion at Redlands have filed suit against the San Bernardino Traction Company for $20,000 for the accidental killing of the animal by one of the cars of that company.

The Santa Fé Company is making extraordinary efforts to make a success of growing eucalyptus trees for tie timber. It's latest step is to send Mr. F. P. Hosp, of Riverside, to Algiers, to study into the various varieties which may be adapted to the uses of the railroad.

HORTICULTURE.

The last of the navels have been shipped from Highlands.

Redlands has an orange picker whose record is 203 boxes in ten hours.

Tomatoes are ripening and being shipped in large quantities from Thermal.

Apricots at Banning are fully two weeks earlier than at the same time last season.

The Imperial Daily Standard predicts a bright future for the grape industry of Imperial Valley.

Abundant olive crops are promised from the present appearance of the trees in most sections of the State.

Brawley is now down to the shipping of cantaloupes in a large way; the shipments now being continuous.

The Linville nurseries, at Highland, have a large force of men planting orange seed bed stock in nursery rows.

Sixty dollars per ton seems to be the prevailing price of apricots in nearly all sections of Southern California

Fullerton has a "lemon squeezer" club; the object seems to be to squeeze the initiate rather than the lemon.

The cultivation of dates in Mecca is progressing, though it will take several years before the experiment will be fully completed.

Thermal claims an output this year of 300 cars of cantaloupes, 5 cars of Malaga grapes, 10 cars of watermelons and 50 cars of tomatoes.

The Duarte-Monrovia Fruit Exchange has declared another dividend on its March oranges, making net to the growers for that month $1.35 per box.

Highlands claims to be the best fitted with cement irrigating flumes of any section in California. A large number of new flumes have been constructed recently.

William A. Taylor, Chief Pomologist of the Department of Agriculture, is in Southern California citrus district inspecting the work of his assistant, G. Harold Powell.

Several ranchers have raised strawberries this spring for consumption at Hemet. The fruit has been large and of a very fine grade, and much money has been made from them.

Placentia Orange Growers' Association claims to hold the record for loading a car of oranges. Five men recently loaded a car with 384 boxes of oranges in fifty-three minutes.

The Los Angeles buyers are in the field at Bakersfield after the early apricots. The crop will be small this season and the southern market promises to be strong for fresh fruit of that kind.

A rancher in Santa Ana exhibits a pound box of berries which holds exactly one dozen strawberries; the largest berry in the box measures five and one-half incnes in circumference.

Horticultural Commissioner Pease of San Bernardino County, is making an active campaign against the cutworms and recommends sticky flypaper as one of the most effective remedies in protecting trees.

The Tustin packing-house, learning of the record of Placentia in the matter of loading a car of oranges, mentions that four men loaded a car with 384 boxes in exactly thirty-eight minutes.

The Claremont Farmers' Club, one of the most active clubs in California, is energetic in its investigation of live questions of interest to horticulturists. Its most recent investigation has been along the line of fumigation, regarding which, a committee, headed by Prof. Cook, has made an extended report.

The Chinaman, with his usual "get there" spirit, is already monopolizing the Panama Canal zone. The government leases the land to them for garden purposes at $3 per hactare, or about $1 per acre. Already 14,000 such leases have been made to Chinamen.

Northern California

AGRICULTURE.

The Marysville creamery is being enlarged.

Butte county is to maintain an exhibit of its products at Oroville.

Red Bluff has an experimental plot of redwoods, which are doing well.

There will be one thousand acres of sugar beets planted near Alpaugh.

Cattle thieves are making depredations in the southern end of Salinas Valley.

The levee of District Number 9, in Sutter county, will be raised during the season.

Experiments in Glenn county in feeding sheep on alfalfa have proven most profitable.

Turlock is to have a new creamery at it's California Alfalfa Colony, in the near future.

Tulare Lake is still reported as rising, being two feet higher than last year at this time.

The Seropian packing-house at Fresno has been purchased by the California Canners' Association.

The Ukiah Valley Times, in a neatly printed supplement, maintains that it is the paradise of the farmer.

The Petaluma Poultry Keepers' Association is planning for a great poultry show to be given this fall.

Wheatland ranchers maintain that the present outlook for hay and grain crops is the finest in many years.

Corcoran claims the biggest turnips in the state; its rich land producing roots nine inches in diameter.

W. F. Mitchell, former manager of Colusa Butter Company, has taken charge of the creamery at Meridian.

Visalia and the country about it had a "clean up" day recently at which weeds along road sides were laid low.

The Hanford Sentinel says some of the most magnificent hay crops ever is the record this year in that section.

The Turlock Irrigation District is offering to sell bonds for the purpose of making improvements in its system.

Tipton, Tulare county, has just completed a new creamery, which is under the management of F. H. Elliott.

Watsonville is hoping for the dredging of the river, which will give her better freight facilities to San Francisco.

A creamery will be built by the farmers and business men of Ukiah; already two hundred cows being pledged.

Dredgers throwing up new levees in the neighborhood of Corcoran are reclaiming some fine land for asparagus planting.

The county road between Grass Valley and Nevada City is being improved and will be sprinkled daily during the coming summer.

The Turlock Journal reports the experiments with patent milking machines by some of the farmers near that section as successful.

A new water rate for irrigationists along the King's River canal makes them pay an increase of 22½ cents per acre over that of last year.

The Sutter county farmer appeals for better protection against the dredging gold miners who are destroying the usefulness of the navigable streams.

The Visalia Delta reports that fine quality of beets are being produced by the farmers of Alpaugh for delivery to the Pacific Sugar Company's factory at Visalia.

Wheat will be light in most sections. The early, heavy and continuous rains in the wheat sections of the State prevented sowing, and the wheat acreage is very small this year and the crops, where sown, are light.

The Farmers' Phone Company, in the vicinity of Woodland, is planning for extensive improvements of its lines; this feature, which has brought so much satisfaction to farm life, is proving very successful to the members of this company.

HORTICULTURE.

Santa Clara country prune growers are being offered 3½ cents for their prunes.

Grape vines about Yuba City are reported doing exceedingly well and a big yield is promised.

The Kerman News maintains that the owner of fourteen acres of Kerman land can support an automobile.

J. A. Graham has an orange orchard of 2046 trees in full bearing. They yielded 4307 packed boxes and the net returns were $6038.78.

The cherry crop in the neighborhood of Yuba City is largely gathered, and while not up to the usual yield still will make a large output.

The Vacaville Reporter says that pears have dropped from the trees badly and the crop will be much lighter than was at first anticipated.

The raising of tomatoes at Red Bluff has proven exceedingly profitable; a large acreage has been planted this year. Most of the output goes to the North.

California Wine Association will extensively manufacture unfermented grape juice, which has been proving so popular with trade during the last few years.

Rus Stephens, of Sacramento, maintains that the shortage of fruit in the Middle West and Northwest is going to give finest of markets for California fresh fruits this year.

The Pacific Pea Packing Company is successfully working its first season's pack at Oakdale. About 12,000 cans per day are filled with peas and stacked, ready for market.

The Fajaronian appeals to the apple growers not to spray apples for codling moth until blossoms have fallen because of the damage to fruit and death to bees that will result.

The Tulare county Times maintains that the subdivision of large tracts of land in the immediate suburbs of Visalia is bringing a great deal of prosperity to that community.

Many contracts for prunes have been signed in Sutter county on a two and a quarter to two and three-quarter-cent basis. Some growers have sold the straight lot, all sizes, for $60 to $70 per dry ton.

The Watsonville Pajaronian says that the oldest inhabitant maintains that he never saw such a flood year end with such a dry spring. Much damage to the later crops has been occasioned by the drouth.

The Fresno Chamber of Commerce has secured the services of Prof. W. W. Mackie, of the Bureau of Soils, Department of Agriculture, who will lecture to the farmers of Fresno on the reclamation of alkali lands.

Residents of Gridley are raising funds to commence suit against the gold dredgers who are working in the neighborhood of Oroville. An assessment of $1 per acre is made upon those who join in the action as a first assessment.

Residents of Southern Shasta county will petition the Government Reclamation Service to establish an irrigation district for their benefit. Waters are to be obtained in the Trinity and Coast ranges. It is maintained the system will cover about 150,000 to 200,000 acres.

Farmers are busy in Sutter county and the late crops of corn, beans, vegetables and alfalfa are likely to be very heavy. After all, the river farmers may do better than some of our high land farmers, who, owing to excessive rains, followed by excessive dry weather, will not harvest very large crops this season.

Deciduous fruit growers are pleased with the new freight rating promised by the Southern Pacific Company, though it is not so favorable as at first announced. There is a ten-cent reduction to many points which was thought to prevail, at first, to all, but some of the larger receiving points of the East will have a reduction of only five cents per hundred.

ALL ABOUT THE
Orange and Lemon
Is told in our new book on Citrus Culture, embracing every phase of the subject from the seedling bud to the final disposition of the fruit in the Eastern market. The largest and best book on the subject ever printed — 50,000 words, 100 illustrations. You will want a copy, which we will send you for the small sum of 25 cents. Remember we are the largest growers of orange and lemon trees in the world.

THOROUGHNESS.

THERE are endless combinations of circumstances that serve to bring failure to the orange grower as with other lines of business. It takes a certain amount of close observation to know just what to do to circumvent such events that tend to bring failure. Thoroughness, if persistently adhered to will cover most of the ground.

It is not alone doing individual things thoroughly, but doing them at the right time, varying only as the demand of the trees or soil necessitates.

It avails little if, for instance, an orange grower fails to apply a remedy for scale a little too late to get the proper effect, even though the job is thoroughly and systemmatically done at the time. There are conditions to be studied in every district and it is the working out of the principles to be followed that brings about desired results, that constitute one part of the scheme of thoroughness. One man may run water on his grove for one day and do a thorough job and his next door neighbor may have to run the water four days to do it thoroughly.

Cut worms are abroad in the land and are doing much damage to some groves. Other groves are not in the least infected. Green crops grown for fertilizers are getting the blame for the loss occasioned by their presence. The green crops attract the worms, it is true, but it is due to the lack of thoroughness, that the green crops are allowed to remain near the tree at worm time. Everybody knows that their coming is entirely unknown till they or the adult insects make their appearance. We can expect them any season. We also know that the weather cannot be relied upon. Looking these two propositions squarely in the face, how can we blame anybody or anything for "getting caught" on the weather. If we stick to the principles of not putting the work off beyond a period that defines the limit of safety the knowledge of this is forced upon us every few years, then we are thorough in that line of work.

This is only a fraction of thoroughness in our work. Bailey says that a good business man will make a good farmer. A farmer who is not a good business man is invariably a poor farmer. Why is this? It would appeal to most of us at least, that a good business man must be thorough. We had a good illustration of thoroughness, very much emphasized, by the lack of it, pointed out to us today. There are two Bartlett pear orchards adjoining the city of Riverside, both having become affected with blight at the same time several years ago. Both are as good land and have equal advantages in that respect. The owner of one orchard has too many things to look after to do a thorough job of attempting to erradicate the blight and went at it in a "general way" and his orchard is now gone beyond help. The other orchard was pruned and cared for by following the instructions given by Waite in his bulletin on treatment of pear blight. He followed the details implicitly everytime he saw the necessity of doing anything. We are told that his orchard paid him as good net returns last year as some of the best orange groves.

There are several orange growers in Southern California who never saw an orange grove previous to a few years ago, but today they are pointed to as the most successful growers in the world. Hundreds of other growers have made a success of the business to just as high a degree, but not being in the business on a large scale they do not attract attention. Nevertheless, they apply their rules and put into practice their ideas as thoroughly as the large growers. In years gone by, with less knowledge of the requirements of the orange tree, many failures were made because of the lack of certain knowledge, and instead of the failure being due to the lack of thoroughness, it was due to thoroughness of doing the wrong thing. Here is where the pioneer does not get fair judgment. The new and successful grower more often than not, owes his success in a great measure, to having commenced where the pioneer left off, profiting by his mistake more than by his successes and applying the principles that have enriched him in former business occupations.

AS VIEWED IN ENGLAND.

That California oranges would ultimately capture English markets has been maintained for years and many scattering shipments have been made. How our English cousins look at our fruit is of interest, so we quote from the London Daily Telegraph. Some of the statements bear the appearance of "hot air" but it may be taken for its worth:

Any addition to the variety of choice fruits is always welcome, and as such, the large, handsome and attractive oranges from California now arriving in large quantities must be counted a distinct acquisition. These oranges are of the seedless variety, and in these days, when every point touching on the absence of risks to health is so carefully considered, the fact of the entire absence of seeds in these delicious oranges is enormously in their favor. The appearance and aroma of California oranges leave nothing to be desired. Of a beautiful shade, and with a bouquet which is delicately aromatic, these oranges will probably find a place in every well-arranged dessert dish. Considerable interest has been aroused by the persistent and strenuous efforts of the Californians to make England a regular market for the disposal of their famous fruits, and their methods of doing business are very commendable. Close upon 4000 growers have formed themselves into a co-operative association, and all are working for their mutual interests. The vast acreage represented is well-nigh incalculable, as in some instances the the groves are 1000 acres in extent. This orginization is controlled entirely by the growers themselves, but it must be understood that none of the American "trust" methods have been adopted. There is no interference with the production, or attempt arbitrarily to fix prices. Heretofore the price of California oranges in England has been somewhat of a deterrent to the general public, but now there is every indication that in the future, with increased supply, the price of oranges will be essentially moderate.

Fifteen years ago the yield of the California orange crop amounted to one million boxes, and the present year's output is estimated to reach ten times that quantity. So large an increase in so short a space of time is a tribute to the energy of the Californian producers, and there is every prospect of still larger quantities. Until within recent years these handsome oranges were entirely disposed of in New York and other large American markets, where they have always met with a good reception, but the enormous increase in the production has been the cause of the Californians introducing their goods into European markets. At the present time Californian oranges are realizing as much on the New York markets as in London, yet it is not to be allowed to interfere with the continued supplies for England, as the growers have definitely decided to popularize their fruit in England even should a large initial loss be inevitable. Every care is taken in the selecting and packing of the fruit, which has been arriving here in excellent transit in about three weeks. The oranges are sent by special trains in car loads (average 384 boxes) to New York, which journey occupies from ten to twelve days; they are then shipped on the fastest available mail steamers to Southhampton or Liverpool. The Californians are living in hopes of the Panama canal being one day a "fait accompli;" and should their sanguine hopes be realized, their oranges and other fruits could be landed in England by means of direct steamers, at much less expense than is incurred in conveying them to New York.

The first orange trees in California were those planted by missionaries, and were more for ornament than use, but in 1874 the government sent to California the first orange trees of the seedless variety. These trees enabled the Californians to commence a new epoch in their fruit growing industry, and have been instrumental in obtaining for the country a world-wide reputation for the production of high-class fruit.

"Why are you always quarreling with your wife?"

"She is always arguing with me."

"But you need not get angry; just explain to her in a calm, gentle tone of voice wherein she is wrong."

"But she is never wrong."

PEDIGREE STRAWBERRY PLANTS.

PEDIGREE plants or animals are those having a known line of ancestry—presumably good ancestry.

New varieties of strawberries originate from seed sown by man or nature. A variety thus originated propagates itself by means of runners which grow out from the old plants, take root and form young plants. A pedigree strawberry plant, as I use the term, means usually, but not always, one of the above kinds (for the ancestry of some of the best varieties is not known), which has been still further improved by repeatedly selecting plants noted for general excellence as bearers from whose runners young plants are obtained to set all new fields.

From these young plants the most excellent ones are again in fruiting time selected, and so on indefinitely. But the berries should not be allowed to remain on these plants an hour longer than is necessary to prove the fruitfulness and general excellence of the plant. The berries should always be pulled before they ripen, or the seed matures, which is the process so exhausting to the plant.

It is denied that this selection does any good at all, and asserted that one plant of any given variety is just as good as any other plant of that variety. That the assertion is erroneous I know from actual and repeated tests. I have long followed this plan of selection and proven that it does tell strongly in the improvement of a variety, provided, of course, that it is intelligently and persistently carried out.

In fact, improvement in plant or animal can come in no other way. To assert that all strawberry plants of any given variety are equally good, no matter how the one may have been allowed to run down by neglect nor the other bred up by careful selection and high culture, is an error, and an error of a very harmful kind.

It is as erroneous as to hold that one herd or strain of Jersey cows is as good as any other herd or strain. Although one might have been highly and judiciously fed and bred only from the best cows and the other herd or strain had been starved and bred from scrubs for twenty generations.

The fact is that all varieties of strawberry plants as soon as originated begin a gradual process of change. It may be slow, but it is sure and almost inevitably tends to deterioration.

My plan is to arrest and even to some extent reverse this process of deterioration by raising young plants from old plants of conspicuous merit and from no others.—Colman's Rural World.

THE COUNTRY GENTLEMAN.

The time is to come when the country gentleman will be recognized as of equal importance with the city gentleman. That time will be when the country gentleman is as well educated and as poushed as the city gentleman. While we have many gentlemen in the rural districts that are well educated, we have a great number that are not as well educated as are the men of the same standing in the city. This is because the opportunities for education in the city are very much better than in the country, and also because the movement of wealth has been toward the cities for many generations.

Polish Up.

If the country gentleman lacks polish in some instances, it is because his social opportunities are less than the opportunities of the man living in the city. But the days are coming when all this will be changed, and the country gentleman will be the principal factor in changing them. It is possible for the gentleman born and brought up in the country to have all the advantages and none of the drawbacks. In the past, material conditions have been against him. The transportation question was so far from being solved that he had to depend on the elements in the city for the movement of his products and of himself as well as to supply him with the necessities of life.

Events are moving rapidly now. The telephone has placed the farmer in close touch with the town. So far as information is concerned, the farmer finds himself as well off as the citizen. The paper that is published in the morning is at his home by night, and he can read all the happenings of the previous day. That includes the market reports, which he may want in greater detail than he could obtain easily over the telephone. The electric line has placed his family in touch with many other families in the country as well as with a still larger number of families in the towns.

Best Schools Possible.

The country gentleman has now the problem of the country schools to consider, and it is a problem that will not down, as it has done in the past. The electric line makes it possible for him to solve this problem more easily than ever before. The country schools, in the main, are poor schools. They are poorly equipped and have poorly trained teachers. In many cases the pay is so small that none but poorly fitted teachers can be secured. The best teachers are snapped up by the city schools. The teacher who wants a permanent place seeks the city school. That is the rule, though there are exceptions. The country gentleman is but looking after his own interests when he demands that the facilities for education in the country be as good as those in the city. These conditions can be brought about if the country people will but give the matter their attention. The matter is receiving attention in some localities, where the country gentleman has taken up the matter and is stirring up the people to action.

MAPLE TREES.

A newspaper published in Shasta county, California, reports that Charles L. Paige, a farmer living on Clear creek, in that county, has this season made twelve gallons of maple syrup from the sap of Oregon maple trees planted within the last ten years. These trees are growing at an altitude of 1500 to 2000 feet. Mr. Paige has decided to plant many more maple trees on the mountainous portion of his ranch and hopes to secure maple sap in paying quantities from them in seven to ten years.

Give early and good cultivation between the rows of strawberry plants, then place the mulch between the rows at the proper time. The mulch will keep down the weeds and conserve moisture.

SIMMONS HARDWARE COMPANY (Inc.), St. Louis and New York, U. S. A.

AND Is Going Up In ALBERTA

You know how many times you have missed opportunities by putting off—The man who takes advantage of his opportunities is the man who gets rich and makes his money easy.

You have heard how people are making money in the rise of land values in Alberta, Canada. Perhaps some of your neighbors have gone there and invested, and if they have they have made money.

But have you taken advantage of the great opportunities offered there?

Land in Alberta is constantly rising in value--It is not very high yet, but it is going up again this year and next year.

Why?

Because in Sunny Southern Alberta is to be found as good land as lies out of doors—Because thousands of farmers from the United States and other countries are going in there and taking it up every year—Because enormous crops of almost all kinds of grain and vegetables can be raised there and sold at high prices—Because it is the greatest cattle, sheep and hog country on earth—Because almost every profitable product of the farm can be raised at the lowest possible cost and sold right at home—Because dairying is more profitable there than in almost any other spot on earth.

Aren't those reasons sufficient to convince you that land is going to continue to rise in value in Alberta.

People have just begun to learn what a a great place western Canada is—They have just begun to learn that it is not the coldest country on earth, but has a fine climate both winter and summer.

People have just begun to learn that there are good schools in which to educate their children, and that the neighborhoods are made up of much the same class of people that they have surrounding them at home in the United States.

You can buy Southern Alberta land cheaper right now than you will ever buy it again.

Write for our literature which tells you all about our irrigated, non-irrigated and combination farms containing both irrigated and non-irrigated lands. We will tell you how to take a fine trip through Alberta at a very low cost, and we will tell you how to buy as good land as there is in Alberta on terms so easy that anyone can own a farm.

315 South Main St. **Henry Albers Co.** Los Angeles, Cal.

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

By JOHN ISAAC, Sacramento, California

A PLAGUE OF CUTWORMS.

THE army worm has again appeared in destructive numbers in many sections of the State and gardeners especially, are complaining of its ravages. There are several species of insects which have the gregarious habit, which, in their larval stage, live in great communities and, by some instinct, move in masses. Chief among these are the cutworms, the young, or larval form, of a night-flying group of moths to which the common name of owlets is applied, from their nocturnal habits, their soft downy plumage and their general shape. As a rule, insects of this class are inconspicuous in color and markings and so strongly resemble the coloration of objects on which they repose during the day as to escape notice. The eggs are laid on low-growing vegetation and as soon as the young worm is hatched, it works its way toward the ground into which it burrows during the day coming forth at night to commit its depredations. Many of them climb trees, shrubs and high-growing plants, and are hence known as climbing cutworms. When they have exhausted the food supply of their breeding grounds, they will start for fresh pastures and sometimes travel in such enormous numbers that one who has not seen them on the march would not credit the extent of their numbers. They will cut through the stems of low-growing tender vegetables and leave a field as bare as though it had been gone over with a mower. The cutworm is a heavy bodied insect and it can be stopped from climbing young plants, as tomatoes, cabbages, etc., by placing a tin cylinder, inserted an inch or two into the ground, around the plant. Old tomato cans, fruit cans, etc., with the ends melted out answer the purpose admirably. Where the pests are marching in numbers, a trench with perpendicular sides dug across their path will trap them in quantities and they can then be destroyed. Poisoned bran has been found an effective remedy for them. Thoroughly mix in a dry state 50 pounds of bran and one pound of Paris green, add water, a little sweetened with sugar, until the whole is thoroughly wet but not sloppy. Army worms are very fond of this mixture, prefering it even to vegetation, and can be killed off by thousands. They eat voraciously of it and then crawl under ground, acting as their own sexton and fertilizing the soil with their bodies.

CALIFORNIA EXPERTS WANTED.

A few monhts since A. D. Chandler, of Brookline, Mass., was sent to California by the citizens of his town as an agent for the purpose of studying California's methods of fighting insect pests with their natural enemies. While here, he made a thorough investigation and made a favorable report. Since then he has addressed several meetings in Massachusetts on the subject, with a view to using parasites in the great fight now being waged against the Gypsy moth in that section. At a late meeting of the Citizens Association of Medford, Mass., at which place the Gypsy moth was first introduced, it was resolved to call upon the legislature for $5000 for "the seasonable examination of the parasite work of Massachusetts in suppressing the Gypsy and Brown Tail moths, to be made by such experts from California as the governor of Massachusetts may approve."

RECOVERING FROM THE FLOOD.

During the high waters of the past winter, when the island sections of the Sacramento and San Joaquin rivers were overflowed, it was feared that on such lands there would be no crops raised this year. It now develops that matters were not so bad as they might have been. The greater part of the water has been drained off, and the land sown. Crops, on such overflowed land, are already well advanced and will give a good harvest. In hop yards which were under water, the vines have been little injured, the water has entirely receded and the land is in better condition than before the overflow. The great asparagus fields are yielding well, and altogether in spite of early apprehensions, little damage was done by the high waters to the farming lands.

INSECTARY FOR GOLDEN GATE PARK.

After the great earthquake and fire in San Francisco, it was discovered that the insectary in the Ferry building had been destroyed and most of the beneficial insects killed. Some arrangement had to be made to save those that were left at once, so temporary quarters were provided in Sacramento and for a year past beneficial insects have been bred there. Being far from the port of San Francisco and lacking in conveniences for shipping and propagating, it was determined to return to San Francisco as soon as possible. State Horticultural Commissioner Cooper, for some time past has been negotiating for a location for an insectary in the Golden Gate Park and the Park Commissioners have at last granted him a site for such building, which is to be erected and stocked immediately. The parasite service, on account of limited facilities, has not been all that could be desired for the past year but it is hoped, with the new building and improved facilities, to bring it back to the standard of its efficiency before the fire.

COMYS FUSCA.

Deputy Commissioner Ehrhorn sends word that all fruit growers who desire colonies of Comys fusca, the internal parasite for the "Brown Apricot Scale" (Eulecanium armeniacum) infesting prune, apricot and peach trees are requested to send in their applications as early as possible —not later than May 25., as this parasite will probably not be available after that date. They are furnished gratis. Apply at the office of

State Commissioner of Horticulture, Room 11 Ferry Bldg., San Francisco.

SPRAY FOR LEAF CURL.

A peach-grower has handed in the following recipe for curl leaf in peach trees that he says is an infallble remedy:

Dissolve 8 pounds of blue stone and 12 pounds of unslacked lime in water separately, when thoroughly dissolved put them together and add 50 gallons of water. Spray trees lightly two times a year, just after picking and again in December. Smaller quantities can be made by using the same proportions of blue stone, lime and water.

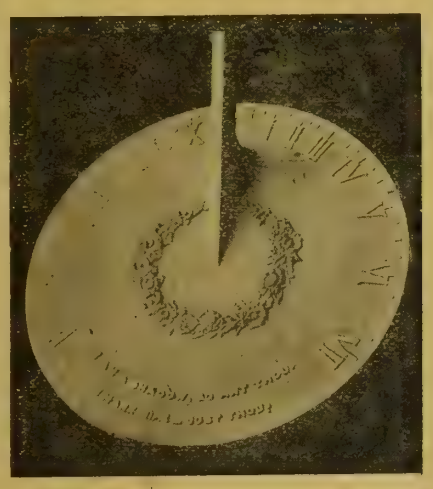
The Ornamental Garden

THE SUN-DIAL.

BEHOLD, I will bring again the shadow of the degrees, which is gone down in the sun-dial of Ahaz, ten degrees backward. So the sun returned ten degrees, by which degrees it was gone down."

In this statement, made in the time of good old Hezekiah, more than seven hundred years before Christ, is a reference to the sun-dial, which, at that time, was the principal means of determining the time of day. For many hundreds of years after that, and probably many hundreds of years before that, some claiming back as far as the beginning of the human race, this picturesque feature occupied a prominent place in many gardens. In recent years, however, it has not been used as in those good old days, because the more useful watches and clocks have given us more corect, or at least more convenient, answer to our question as to the time. Be that as it may, this picturesque feature of the garden has offered to many opportunities for beautifying cozy nooks in the garden. In more recent years, the more wealthy garden makers



have brought it back to life and the interest which it inspires on the part of those who see it for the first time has been such that it is greatly increasing in use. Some of the most beautiful lawns in our larger towns and in our public parks have added this feature.

In the City of Los Angeles, Mr. Wesley Clark, Judge Silent, Mrs. Geo. Goldsmith, and the Barlow Sanitorium are among those who have seen the beauty of this historical timekeeper. These were constructed and placed by Mr. W. A. Seymour, a man who has given much study to the construction of sun-dials.

The art of constructing sun-dials at, and before, the time of Christ to suit any place and situation was an important branch of mathematical study. Today, it is more of a matter of curiosity, and a few like Mr. Seymour, study its more technical features and are prepared to erect these dials to fit any situation, or to be placed in any latitude. They are usually constructed of bronze or of brass, though we have seen them of immense size constructed of wood with the gnomon, or style, extending several feet into the air, and parellel with the earth's axis, or in other words, pointing directly at the north star. Thus the sun's shadow falls upon figures made by the gardener in flower-beds in a circle on which the shadow of the style may fall.

This form of dial is less common and not so picturesque as the pedestal with a bronze plate on which may be moulded a motto or inscription according to the taste of the garden owner. The one shown in the illustration on this page is a very apt inscription. Amongst others we may mention: "I only reckon the bright hours." Which may be taken as a pretty good motto for us humans as well.

"Time wastes us, our bodies and our wits,
And we waste Time, so Time and we are quits."

"Abuse me not, I do no ill,
I stand to serve thee with good will;
As careful then be sure thou be,
To serve thy God as I serve thee."

"The hours which my faithful shadows point out to thee,
Remember, have been taken from thy life."

"The last hour, to many, perhaps to thee."

"As a shadow, such is life."

"I mark not the hours unless they be bright,
I mark not the hour of darkness and night;
My promise is solely to follow the sun,
And point out the course his chariot doth run."

CATALPA.

The growth of this tree is rapid. Three and four-year-old trees furnish quite a good deal of shade. However, for cross ties and for other purposes the trees must be at least 15 years old from seed. I have known trees which were claimed to be 100 years old and 4 or 5 feet in diameter. The wood is not very strong, but lasts well, either as posts or for ties. I know of catalpa posts which have been in the ground 30 years and are still sound.

Be sure and get Catalpa speciosa. Another variety, Catalpa begnoniodes, is a very inferior tree. It seeds more freely than the other variety, consequently in many places is more common. It is a smaller tree and the wood does not last as well. The only way of telling the difference in the seed is by the size and number. Catalpa speciosa has the largest seed, but there are not very many seeds to the pod, while the other variety has a great many in each pod.

The desirable variety grows well in nearly all parts of the United States and there is no reason why it should not be planted more largely than it is at present. It is a beautiful tree for ornamentation, as it bears large, white blossoms in the spring, making it very attractive. However, the leaves fall early and for that reason it is objected to by many for ornamental purposes. The seed can easily be obtained from nurserymen. —Ex.

DESERVED TO LIVE.

In a rural justice court in Georgia recently an old negro, whose testimony had been questioned, said in his own defense:

"Jedge, I'm a good man. I been a-livin' roun' heah ten years. I ain't never been lynched; en de only horse I ever stoled throwed me en broke my two legs!"

Sugar Beet Pulp
(Kow-Sauer-Kraut) For Cows

Q. What is a cow?
Ans. She is a square critter, with a peg at each corner to stand on.

The Cow Talks: I have also been called a "milk-machine." To a nail-machine they feed wire and get nails. So they expect to feed me wire-y, dusty musty hay and get milk. Nothing in it. Don't expect to get wire nails from a nail-machine without feeding it wire, nor milk from this milk-machine when fed on wire-y hay mostly trodden under my feet.

I'll tell you what to feed me—give me Kow-Sauer-Kraut when I come in from the pasture.

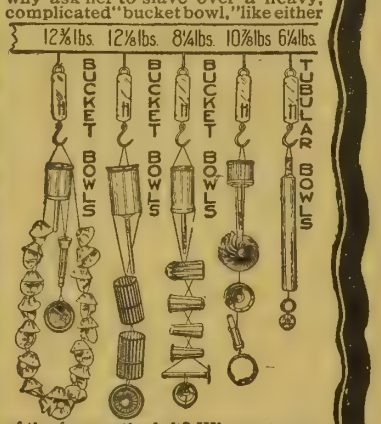
Kow-Mathematics: Then I'll give you 32c worth of milk for a cent's worth of pulp. Besides, I figure I'll get fat at the rate of about a pound a day. (MRS.) A. LEAN COW.

P. S. You can get cured Kow-Sauer-Kraut at $1.00 per ton from the silo of the

Los Alamitos Sugar Co., Los Alamitos, Cal.

Saves Hours of Cleaning

Of course your wife would try to wash even the worst cream separator bowl properly twice every day. But why ask her to slave over a heavy, complicated "bucket bowl," like either



of the four on the left? Why not save her hours of cleaning every week by getting a Sharples Dairy Tubular Cream Separator with a simple, light, Tubular bowl, easily cleaned in 3 minutes, like that on the right? It holds the world's record for clean skimming.

Sharples Tubular Cream Separators are different—very different—from all others. Every difference is to your advantage. Write for catalog M—260 and valuable free book "Business Dairying."

CORN.

THIS giant grass is a native of the new world. Indeed so little was its food value known in the old world that only a few years ago the United States Government maintained corn food shows in the principal cities of the old world where practical demonstrators made corn-bread and Johnny-cake to give to the visitors. I had an artist friend, that came from below the Mason and Dixon line; one day he was strolling along in Munich feeling very far from Dixie land, when a familiar whiff in the air carried him back across the sea. He paused and drew a long breath, looking around he saw a small shop filled with frauleins and pushed his way in, to see corn bread passed out to taste. He waited and was allowed after the crowd had gone away to make some corn cakes. The joy of the familiar taste was heaven to him. Now the people of Europe are using corn after American methods instead of merely regarding it as cattle food.

At present the corn crop has a value that does not make it the cheap adulterant of wheat flours. The Pure Food Law forbids the use of corn in wheat flour. The bread, however, is certainly better when a little corn is added to it, a teacup of fine white corn meal added to each five cups of wheat flour used in bread baking makes a better keeping bread than when it is made with plain white flour.

Planting.

Now is the time to sow the corn field. From the first of April to the Fourth of July corn can be planted and a crop matured in the valleys of California. In the coast regions where irrigation is not practiced the corn is usually sown earlier than in the interior. The interior valleys have later frosts, not usually heavy enough to damage fruit, but little light frosty fingers laid morning after morning on the tender corn blade as it springs from the ground retards its growth. It is a little discouraging to anything to meet a cold reception on its first peep at the bright world. So the corn when discouraged stands still for a while before starting off into vigorous growth. Now, while it may be good for spiritual growth to stop and listen to the life forces around, it is not conducive to bodily vigor for the corn plant to turn to growing anything but a vigorous body.

Vigor.

The secret of growing any crop to perfection is in making its surroundings perfect. There must never be a halt or stop in the growth of an annual crop. The lost time is never caught up again. The time therefore to prepare the soil and make the conditions perfect is before the crop is sown at all. Then watch it grow! It seems to leap out of the ground almost by magic; first the tender blade, then the tassel and then the full grown ear. Before the mind has grasped the wonderful beauty of the plant the leaves are yellowing and harvest is at hand.

Maximum Crops.

In growing corn in California we have been satisfied with a minimum crop. A little selection of seed and a great deal better cultivating of the ground would enable us to do as well as the farmers of the Middle West. Sun, water and soil we have of the best. The sun in the San Joaquin Valley, it never fails us; it is our pride that we have more sunshine than any where else in the world. Whew! when it soars up, it knows how to stay up in the sky, during the long, long July days. The leaves rustle and crackle on the vines and trees; they are full of the eager joy of growth.

The water comes freely from the mountain streams down the canal, clear, bright, cool, soft water and the thirsty land drinks its full, for there is no cement lining in these ditches and the water sub-irrigates the land freely. Now, with all this the yield of corn is only about half of the maximum crop of the corn-belt states. Half the growers of corn fail to realize more than 25 bushels to the acre. One hundred bushels to the acre should be produced many seasons. Fifty bushels is now looked upon as a fair crop while seventy-five is a good crop. Yet the hundred bushels has been frequently reached so that it is not asking too much that here where we have conditions under control, as to heat and water, that this should be our expected crop. We fail in cultivation, for the New England crops with a short summer and poor soil average more bushels per acre of corn than any other portion of the United States.

Alfalfa.

Corn and alfalfa! Alfalfa and corn! Which shall we place first as the greater food for the stock man? Together they so perfectly supplement each other that the great stock countries of the world should grow up where both these crops grow to perfection. The corn crop in the East when it fails is usually owing to weather conditions. When it fails in California the two reasons are, poor seed and poor care. The seed of the best dent variety should be purchased in the East from the grower, and then after it is grown here, make a selection of the best ears for seed. Gather from the stalks that have two or three well developed ears to a stalk, twice as many ears as there will be needed for next year's crop. Then some leisure days spread the corn on a table in the packing house and select the ears that have perfectly developed grains of even size to the end of the cobs. Repeat this selection from year to year and the corn will improve rapidly.

Varieties.

Naturally in an article like this the people skim through it and ask what varieties are recommended. Now I find that a hard question to answer, because corn cross-pollinates freely and the same variety by name grown in different sections of the country is quite a different appearing corn. I have found the best way is to buy a dent corn from a careful grower in the East. I received three weeks ago a new supply of two hundred pounds from Lancaster County, Pennsylvania, from a man that has raised banner crops for several years. The freight on the corn was six and a half dollars so you see that it costs something when it arrives here. This corn will, however, last as a start for eight or ten years. Enough will be sold

from next year's crop to the neighbors to pay for bringing it here.

Irrigation.

The first steps to be taken for the corn crops on the ranch will begin the end of next week, or as soon as the hay is cut and made on the oats field. The land will be roughly irrigated, then enough furrows run to carry water to completely soak all parts of the land. When this is finished the disks will run over it both ways, and then the plows will follow to throw out a deep furrow. This furrow will be down ten inches below the surface, the furrows will be four feet apart.

The cultivators are run on the space between the furrow down deep to make the soil loose and friable to retain the moisture; while this is being done the corn planter is at work putting in the corn in the furrows. After a few days the corn is up and the cultivators are run to keep down the weeds. Now, in calling the furrow ten inches deep it is understood that the aim is to have it that deep, but in actual practice it will average six inches only. In this world we have to follow Emerson's advice and hitch our wagon to a star. In laying out the work we must tell men ten when we expect to average six or seven at most.

HOW TO FEED A DAIRY COW.

A practical dairyman writes the Jersey Bulletin on feeding his cows. He says: "Our herd numbers in all fifteen head. Our cows are grained the year round, have the run of pasture in summer, and are well housed in winter. Our summer ration for a dairy cow is barley chop, about four pounds per diem. In winter we use shredded fodder for roughage; grain ration, eight pounds per day per cow of a mixture of cornmeal, barley meal, malt sprouts and cotton-seed meal, mixed in the required proportions to produce a feed which would analyze one part of protein to six of carbohydrates. Our cows are not allowed to stand alongside a straw stack for shelter when the thermometer shows something a little less than zero, but are kept in the stable, and even watered there.

PURE WATER A NECESSITY.

A New Zealand agricultural journal says: "Dairy cows have the ability to make pretty good milk when drinking pretty bad water. They would drink more water and make more and better milk if they had better water to drink. It has been proved over and over again that tainted water will impart its taint to the milk of cows which drink it. Not only this, but cows drinking from sagholes holding stagnant water cannot be kept in healthy condition any more than can people. We know how careful people are with regard to their drinking water.

"Cities spend thousands and thousands of pounds in getting a pure water supply. There is no more common source of sickness, disease and death than impure drinking water, and it is just as necessary that a cow should have pure drinking water as a person. There are numerous instances on record where bad flavors in milk, butter and cheese have been traced to an impure water supply for cows, and when the water supply was changed the bad flavor disappeared."

MIXED RATIONS.

The Kansas Experiment Station has completed a feeding test with hogs in which corn, alfalfa and meat meal were used. The hogs were divided into three lots of ten each and feeding commenced October 9, 1905, and continued for 112 days. The initial weight of each hog was about 100 pounds. The first lot consumed 7690 pounds of corn meal or 6.86 pounds per hog per day and gained .99 of a pound per hog per day. The second lot consumed 7848 pounds of corn meal and 1552 pounds of meat meal, being seven pounds of corn meal and 1.38 pounds of meat meal per hog per day, and they gained 1.76 pounds per hog per day.

The third lot consumed 7875 pounds of corn meal and 1340 pounds of alfalfa per day, being 7.03 pounds of corn meal and 1.2 pounds of alfalfa hay per hog per day and they gained 1.18 pounds per hog per day. The corn meal was valued at 62 1-2 cents per 100 pounds, the meat meal at $2 per 100 pounds and the alfalfa hay at 40 cents per 100 pounds.

The cost of gain was $4.33 per 100 pounds for lot 1, $4.13 per 100 pounds for lot 2 and $4.05 per 100 pounds for lot 3.

With corn meal alone it took 692.8 pounds of meal to make 100 pounds gain, a much poorer showing than the average of such experiments.

ALFALFA AND BRAN.

"It is not generally known," says the Journal of Agriculture, "that a ton of alfalfa contains practically as much protein as bran. The farmer who is paying from $20 to $25 per ton for bran to feed his dairy cows would find it much cheaper to raise alfalfa."

Prof. Henry, formerly of the Wisconsin Station, and an authority on feeding, says that "when we compare alfalfa with wheat bran we find that the former is practically the equal of the latter in protein. It would seem that the alfalfa plant offered a solution of the grain feeding problem in this day when the price of mill stuffs is soaring upward. Alfalfa can be grown in nearly every section of the country. There are some things that we may have to learn about the culture, but we should set about to learn that something as soon as possible."

We occasionally hear dairymen lamenting the fact that bran has advanced in price so rapidly that it is no longer a profitable dairy feed. This need not alarm anyone who resides in sections where alfalfa can be grown."

Put a mixture of salt, soot, wood-ashes and sulphur into a box or trough and leave it where the cows can get at it. They will keep healthy with but little dosing with other medicines. Soot is a liver corrector.

Cows that have grain feed regularly will eat corase fodder up cleaner than those wholly upon hay and straw, they have a better digestion.

Slop-fed hogs should have a little solid food every day such as corn, boiled potatoes, etc. See that they have a dry bed every night. Damp sleeping places cause rheumatism.

The Greater National Dairy Show will be held at the International Live Stock Exposition building, Chicago, October 10 to 19.

STRONG and DURABLE

Compact, all the parts accurately made, finely adjusted and working together smoothly; and at the same time, strong, well built, easy to keep in order and light running—these are the features you want to find in a cream separator before you buy one. And when you see a

U. S. CREAM SEPARATOR

you wont have to look any farther. It has them all. That's why it outwears all other makes.

Durability is what the "cheap" separators lack, yet it is most important. We have received letters from many users of the U. S. Separators who have run their machines every day for 10 years and more with entire satisfaction.

Our big, handsome, new catalogue shows plainly all about the construction and wonderful skimming records of the U. S. It will interest you. For free copy write us this way, "Send catalogue number A 20", addressing

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Profit in the Poultry Yard

By FRANK H. THOMAS, Los Angeles, California

DOES POULTRY CULTURE IMPROVE THE BREEDS?

WE know of nothing that has been so improved, by carefully selecting and breeding, as poultry. We are told that all our domestic fowl originated from the jungle fowl, whose only duty was to lay a clutch of eggs, from ten to fifteen, hatch them, and raise what she could. Those of us who have seen the original jungle fowl, from the jungles of India, know that they are far from ideal, and that a bird that will lay only one clutch of eggs and then set could not be bred with profit in this day and age of the world.

Not So Far Back.

But it is not necessary for us to go so far back to get our comparisons—say twenty-five years ago, yes, ten years, and see what we can find and the improvement that has been made. Take the standard bred Barred Rock of today and ten years ago. In looking over show reports we find that the scores ran as high on an occasional bird as they do today; in other words, we will admit that specimens were bred as near standard requirements as they are today, but what we wish to impress on your mind is that where we found one specimen that would score 93½ points then, we will find ten today. In other words, we had ten times as many culls then, as we do now; that our flocks have been selected and culled until they will reproduce themselves to a marked degree.

The Utility Side.

So far we have looked only to the fancy, now let us study the utility or practical side. Some will tell us that in breeding standard bred poultry, we lose sight of the utility points, but this is a mistake. We will take the man who breeds any standard variety and follow him through one season. After he has his pens mated, he will give them the best possible care and treatment to get them to laying as early as possible, as he must have early eggs and chicks for his early trade; unless he can get them to laying early in the fall, and keep them at it all winter, he will not reap the results of an early trade of eggs for hatching. After he hatches his chicks, they are pushed to the limit. They are culled early, if they are Mediterraneans. The cockerels are sold very young for squab broilers, thus giving more room for the care and development of the pullets. If he has the larger breeds, the culls will be, very often, fed for fryers or roasters, but he will have his pullets separated early and developed to sell for early breeders and show birds.

Thus we see that every effort is used to improve his flock, only his best birds, those that have proven to be good layers, are kept the second year for breeders.

He can't afford to let his hens set, as he can make more by using them as egg machines and hatching with incubators.

Two-Hundred-Egg Hen.

How many of us, ten years ago, ever thought of a flock of hens, or an individual, that would lay two hundred eggs in a year. We saw an occasional advertisement, or read an article, that some one had a hen that had laid two hundred eggs in a year; but most of us looked on it as a fairy tale, but today we have the two-hundred-egg hen and even better than this, and this has been accomplished only by careful breeding and selecting.

This selecting can be done in many ways. One can watch the hens and pick out those that are never seen on the nests, or there are a number of books published that will greatly benefit one along these lines. In the near future we expect to publish an article compiled from the report given out by the Polytechnic School at San Luis Obispo, in which only simple methods were used that can be applied on any ranch, or even by those who have only a few fowls on a city lot.

Size Increased.

Not only has the egg production been improved, but size and early development have been carefully considered in every instance. The specialty clubs have sought to improve and encourage the different breeds and varieties by offering special prizes at the exhibitions, and getting up special catalogues, publishing the good points of the different breeds. They have also had members and special committees to meet with the Revision Committee and in many instances have the standard weights raised from one-half pound to one pound on each bird.

AROUND THE YARDS.

We read much about care and condition of yards and runs. The first and about the only thing we read is to spade up the runs, turn under their accumulated filth. This is very good but spading is not sufficient for all kinds and conditions of soil. If you have a sandy, or sandy loam, that does not bake, spading and cultivating is all right; but should your soil be 'dobe, or soil that bakes, as some does it would take a pick to turn it. The best kept yards that we ever saw were treated each spring with a coat of sand or gravel to the depth of several inches. As the sand would get foul it was raked up and put in a pile in some convenient place. When there is enough to warrant, you can take the garden hose and wash it, the filth will settle to the bottom; you can use the clean sand again and the loss of sand will not be great.

Mrs. H. A. N., Santa Ana, writes for instructions for proper housing of brooder chicks after they are taken from the brooder to prevent crowding.

Chicks when taken from the brooder should be put in runs with a colony house for each run, and only chicks that are of one age should be confined to a run, as the larger ones will crowd out the smaller ones at feeding time and will tramp on them at night, thus killing and injuring the weaker ones. Your roosting house should be large enough to comfortably house the chicks confined to the yard or run. To prevent crowding, and to teach them to get up on the perch at night it is well to have a slat floor about three or four inches from the ground made of lath turned edgewise, about one-half inch apart; above these about four inches, you should place your roosts. The chicks will take to the perch very quickly; after they have learned to roost on the perch the slat floor can be removed and cleaned, ready for the next colony.

Don't neglect the houses and nests these warm days, as the vermin will soon get a foothold; it is much harder to get rid of them, after they get a good start, than to keep them down in the first place.

FATTENING CHICKS.

There is probably no animal on the farm that is capable of making more economical use of food consumed than is a young pullet or a cockerel. As a general rule farmers market their pullets and cockerels before they are in the best condition for marketing. They should be fed for at least three weeks prior to shipment. In the corn belt there is probably no grain better adapted for fattening chicks than corn. During the first two weeks of the feeding period, however, it is well to mix with it more or less of animal food. Some of the large poultry feeders use as much as 20 per cent of animal food mixed with the grain ration. It is questionable whether such a large quantity can be used with economy on the average farm, for the reason that intensive feeding is seldom practical, and the consequent needed care is not usually given, but as much as 10 per cent of animal food mixed with the corn ration should give good results.

For fattening purposes it is better to fed ground corn and, if possible, to moisten it with milk. Milk is rich in proteid matter and helps balance the ration. The last week or ten days of the feeding period corn may be fed to the exclusion of all other feeds. Bear in mind tuat when feeding chicks for the market they should not have too much exercise. During the first two weeks they may run about in a comparatively small yard, but during the last week or ten days better results will be secured if chicks are penned up in very small pens where they can practically secure no exercise at all. Some of the large English feeders allow their chicks no exercise whatever. They feed them on the intensive plan and in many cases use what is called the cramming method. For two weeks they feed the chicks all they will eat of ground feed, such as hulled oats and barley mixed with milk, and as soon as the appetite of the chicks wanes they force the feed into their crops by means of a machine especially constructed for that purpose. In this way it is claimed that more rapid gains are secured and the meat of such chickens is also very tender and juicy. —Farmers' Tribune.

WATER GLASS.

Three months ago I put down fifty dozen eggs in wooden pails using silicate of soda, nine part of water to one of soda. I covered the pails tightly as possible but lately noticed some evaporation. I have just transferred them to a barrel and found in one pail the liquid had become about like jelly and the eggs in the bottom were attached to the wood with a white, hard sediment so that the shells were broken in detaching.

I secured the soda from a large San Francisco firm and it was supposed to be pure. It is about the consistency of light syrup and of a light amber color. Can you tell me what causes the eggs to adhere to the wood and is it right for the liquid to become like jelly after a few months? It will be necessary to wash or wipe thoroughly every egg when taken from the liquid (or jelly); will this injure them?

We think the trouble with your eggs is that you did not use enough water in the first place. You should use one part silicate of soda (or Water Glass) to ten parts of water. Some time back the Cultivator published an article of some length on preserving eggs with soda (or Water Glass) and

Why Poultry Die

An enormous amount of money is lost to poultrymen through simple neglect. Hens die for want of a proper tonic to prevent indigestion or ward off disease. All fowls, especially those in confinement, need a corrective or tonic—something to assist digestion, and compel a healthy activity of each organ.

DR. HESS Poultry PAN-A-CE-A

is such a tonic. It contains iron for the blood, and nitrates to eliminate poisonous matter from the system. Poultry Pan-a-ce-a is not a stimulant; it acts in a natural manner, compelling the organs of digestion to convert the largest possible amount of food into bone, muscle, feathers, eggs, etc. Hence, it makes the hen healthy and prolific.

Dr. Hess Poultry Pan-a-ce-a has high medicinal properties, being a cure for gapes, cholera, roup, indigestion, etc., and by its special germicidal principle, it destroys the cause of nearly all poultry disease. It is the prescription of Dr. Hess (M.D., D. V. S.) and is endorsed by the leading poultry associations in United States and Canada. **Sold on a written guarantee. It costs but a penny a day for 30 fowls.**

Stock For Sale. Write for Circular

Mrs. C. D. Hubbard, Box 282, San Fernando, Cal.

from which we reproduce the following:

Directions for Use.

The directions for use are: Use pure water which has been thoroughly boiled and cooled. To each ten quarts of this water add one quart of water-glass. Pack the eggs in the jar and pour the solution over them.

The solution may be prepared, placed in the jar and fresh eggs added from time to time until the jar is filled, but care must be taken to keep fully two inches of water-glass solution to cover the eggs.

Keep the eggs in a cool place and the jar covered to prevent evaporation. A cool cellar is a good place in which to keep the eggs.

If the eggs be kept in too warm a place the silicate will be deposited and the eggs will not be properly protected. Do not wash the eggs before packing, for by so doing you will injure their keeping qualities, probably by dissolving the mucilaginous coating on the outside of the shell. For packing use only perfectly fresh eggs, for eggs that have already become stale cannot be preserved by this or any other method, and one stale egg may spoil the whole batch

"LIMBERNECK."

I have a disease amongst my chickens. They seem to get weak in the legs and in a few hours get paralyzed in the neck. They are not able to hold their heads up.—J. W. Mc.

We presume by the brief description you give, your fowls have what is known as limberneck. This should be prevented by proper feeding and treatment. You should first find the cause and remove it.

We reprint the following from the Reliable Poultry Journal, which gives the best information and remedies we have seen on the subject:

"Limberneck is a partial or temporary paralysis of the neck muscles, usually due to intestinal irritation from worm parasites, acute indigestion, colic, crop inflammation or similar troubles.

Frequently limberneck occurs where chicks or fowls have eaten large quantities of maggots or other indigestible and poisonous matter. In such cases the only treatment is to remove the cause as soon as possible. One of the most satisfactory routine methods of treating limberneck is when the case is first discovered to administer a small dose of oil of turpentine mixed with sweet oil. For little chicks, 2 to 10 drops of turpentine mixed with an equal amount of sweet oil will be found sufficient, according to age. Adult fowls may be given from one to two teaspoonfuls of oil of turpentine mixed with an equal quantity of sweet oil. Where this larger quantity is given it is usually best to administer it through a rubber tube passed directly into the crop. For little chicks the oil may be mixed with dry bread crumbs and given in the form of pills. Birds should be kept warm and quiet. Fifteen minutes to half an hour after the dose of oil of turpentine is given, give warm sweet milk to which has been added a little ginger. One teaspoonful of finely powdered pure ginger thoroughly mixed with half a cup of hot milk and barely sweetened,— of this little chicks may have from one-half to one teaspoonful every hour, and adult fowls may have from one to two tablespoonfuls.

Another good remedy for adult birds is to use a pill made as follows: Equal parts of pure lard, cayenne pepper, powdered ginger, and mustard. Rub all together until thoroughly mixed, divide into pills or slugs the size of a kidney bean. Give one of these pills at a dose and repeat in three hours if necessary. The bird will usually show signs of improvement at once, and in from 10 to 24 hours will be ready to go back to the regular food ration. At first it is best to give only a little food like thoroughly cooked boiled rice lightly seasoned with salt. Follow this with raw vegetables and a limited supply of dry grains, and pure beef scrap. Some cases where there is evidence of intestinal obstruction will be benefited by injecting one or two teaspoonfuls of castor oil mixed with an equal quantity of glycerine directly into the rectum. This may be followed with an injection of one or two ounces of luke warm water."

THE SITTING HEN.

It is true that the incubator is displacing the time-tried biddy in a great many poultry yards, yet the poultry field is very large and many thousands of hens are yet employed, especially by the farmers. We have used both methods and with quite good success, yet we like proper care of the hen and the natural method best this season as well as last will have our hatching done entirely by her again. Much depends upon her care during the winter season as to her ability as a successful hatcher. Hens from an ill-kept flock will not give good results.

If you would have early hatching done by the hen method we must care for the hens during the winter and have them produce as many winter eggs as possible. By getting them to have their laying season over they will come broody during early spring and we are enabled to get out early chicks.

There are two classes of hens that will make winter layers successfully—early-hatched pullets and one-year-old hens. It is possible to get the hens to produce winter eggs very readily, and with this done we are guaranteed early sitters.

Hens that are expected to sit and hatch successfully must not be infested with vermin and disease. Dust baths are very essential and must be supplied. We arrange boxes with our poultry house and hatching apartments filled with dry dust, ash-sifting with a sprinkling of lime and sulphur and some good, reliable insect powder. This is always supplied to the fowls while they are yet laying, thus warding off all attacks of vermin. The large gray louse that attacks the little chicks comes from the body of the hen and if she is allowed to become infested with vermin this trouble among chicks is serious, as their tiny bodies are very delicate and will not stand much sapping of vitality.—Ohio Farmer.

Keep the setting hens in some closed shed or coop away from the other fowls, where they will not be disturbed and after the chicks are hatched keep the old hen cooped until they are weaned. Never let her leave them about, and there will be more chickens at the end of the season. One will lose no chicks during a thunder storm if the hen is under a tight coop; of course, she would rather take them under the eaves of the barn if she could. Don't keep hens after they are two years old, and get new roosters every year.

Regularity in feeding will teach the fowls to be regular in their habits. If they learn that they will receive no food until a certain hour, they will not expect it, and will scratch and work until the time arrives for feeding. Habit will make them punctual, and will save time and annoyance in many ways.

WHY NOT SWAP SKIMMING FORCES?

And have an easier time.

And more dollars for the work you do.

You can come near to doubling your dairy profits—perhaps even more than double them—simply by swapping the force of gravity for centrifugal force in the skimming of your milk.

Suppose we get right down to rock bottom regarding this skimming business.

Cream and skim-milk don't separate just to accommodate anybody, but because some force compels them to.

There are just two forces known to man that can be used for the profitable skimming of milk. One is the force of gravity—the old-time crock, pan or can setting system in use ever since man learned how to milk. Let us take a look at gravity systems first and the other and stronger force afterward.

Gravity is the force that pulls every object downward—the force that gives all things weight. The force of gravity does not change. A pound is a pound the year around. When milk is set in pans, crocks or cans, the force of gravity pulls down on every particle of skim-milk or cream the crock, pan or can contains. But this force of gravity pulls harder on the skim-milk particles than on the butter-fat particles, so that we say skim-milk is heavier than cream, bulk for bulk. In

consequence of this difference in weight, or pull of gravity, the skim-milk settles down and the cream is squeezed up. But not all the cream is squeezed to the top. Some of it fails to rise. There is a reason for this.

When milk is set away in pans, crocks or cans, it begins at once to grow stale. One of the constituent parts of milk is the caseine or cheese part. The instant milk begins to grow stale, this caseine or cheese part begins to coagulate or thicken. It first forms a sort of invisible net or web all through the milk and this web grows gradually thicker and thicker until it forms the solid curd or clabber of sour milk. This web cannot easily be detected until it has become very thick, but it is there, even though we do not see it. As this web forms it entangles and holds fast many of the butter-fat globules. The force that skims the milk must be strong enough to put the entangled fat globules out of this cheesy net or a considerable portion of the butter fat will be left in the skimmed milk and be lost.

Gravity is weak. Being weak, its effect is slow. Being slow, it allows the caseine net to form. Because it is weak and slow, gravity must be allowed, say, twenty-four hours to skim a batch of milk. And all that time the milk and cream are standing round taking up odors from the air, growing stale or sour, and the fat entangling caseine web is getting in its work to your loss. The result is bad in every way. The loss of cream frequently amounts to from one-third to one-half; the other third or half is left in the skimmed milk and goes to make six-cent pork or veal instead of twenty-five to thirty-five-cent butter. The cream that is secured will be off flavor, the butter will show the effect, and stale or sour skimmed milk is not the best sort for your young stock, even though such milk be warmed before feeding. In this way gravity causes the dairyman a great falling off in quantity and quality of butter and in the value of the skimmed milk. This figures up a heavy cash loss in a year.

Is it any wonder that the dairyman who uses a gravity system fails to make dairying pay?

But how about this other and newer skimming force—this centrifugal force? How does it work? How strong is it? What does it accomplish that gravity fails to do?

Centrifugal force is the power that makes whirling bodies pull away from the center about which they are whirled. When a vessel containing milk is rapidly spun around, top like, centrifugal force is generated and pulls outward on the particles of skim-milk and cream. But centrifugal force, like the force of gravity, pulls harder on the skim-milk particles than on the cream particles, so that the skim-milk is drawn outward against the sides of the vessel and the cream is squeezed inward toward the center. Add to this spinning receptacle proper driving mechanism and proper tubes for drawing off the skimmed milk and cream into separate vessels, and you have a centrifugal cream separator—a machine that separates cream and skim-milk by the use of centrifugal force.

The most interesting and valuable characteristic of centrifugal force is this—its strength or power can be increased as greatly as necessity requires. That is the great advantage centrifugal force has over the unchangeable, weak force of gravity. Centrifugal force can be made strong enough to do perfectly and almost instantly what the force of gravity does incompletely and slowly.

This centrifulgal force, being actually ten thousand times stronger than the force of gravity, does thoroughly, and almost instantly, the skimming that gravity would do but imperfectly in twenty-four hours.

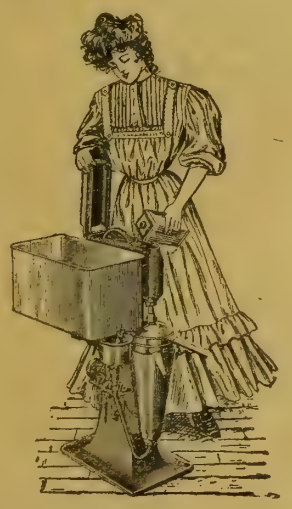
The gain in the centrifulgal force is:

(1.) A skimming force which may be made ten thousand times as strong as gravity, the amount of force depending upon the make of cream separator you select.

(2.) A gain of one-third to one-half—sometimes even more—in the quantity of butter you get from the same amount of milk under the same conditions, the amount of increase depending upon the kind of separator you select.

(3.) A gain in butter quality that will usually run from five to ten cents per pound, according to local conditions, the increase in quality depending partly upon the simplicity of the separator you select.

(4.) You will have fresh, sweet skimmed milk, still warm with the heat of the cow, which will be much better for your young stock than the stale, sour or diluted skim milk from pans, crocks, cans, or creamery.



(5.) You will have a single can of cream to set away or haul to the creamery instead of several crocks, pans or cans of whole milk to care for, and your trips to the creamery will be decreased by at least one-half.

(6.) You will require less storage room, less ice and practically no pans, crocks or cans, thereby greatly reducing the cost and labor of handling milk and cleaning milk utensils.

Do not make the mistake of thinking that the man who hauls his whole milk to a creamery and carries the skimmed milk back has solved the problem, for this man gives—wastes would be truer—his own time and the time of his team and wagon in making his daily trip. Every pound added to the load he hauls sinks his wheels so much the deeper into the mud or wrings the sweat so much the more freely from his horses. He must haul one load each way every day. In addition, the man who takes skimmed milk home from the creamery gets a stale article, diluted with washings, which may be the means of introducing into his stock tuberculosis or some other disease which afflicts some neighbor's herd.

The illustrations used in this article have been loaned to us through the courtesy of The Sharples Separator Company of West Chester, Pa., Chicago, Ill., and Toronto, Canada, manufacturers of the Sharples Tubular Cream Separator.

Should any of our readers desire more knowledge on this subject, we suggest that they write for a copy of a very useful book called "Business Dairying," which the Sharples Separator Company offer to mail, free, upon request. Be sure to mention the name of this paper when writing for this book, thus insuring the very promptest attention to your request.

Richest Farm Lands In California

Are those found in Kings and Tulare Counties, where sugar beets, alfalfa and fruit return immense profits.

Dairying

proves highly remunerative and stock raising is better than banking. These lands are selling for $25 to $30 per acre. Profits follow improvements. Over $1,500,000 invested on lands owned, sold and developed by this Company.

Corcoran

The center of this tract of wealth, is a magic town, provided with every advantage of railroads, water and electric lights, and is a marvel for its age.

Government Whitewash.

We wish to make a whitewash that will stick on out buildings better than milk-of-lime alone. Will you kindly give us a pointer? Also can such a wash be put on with the spray pump?—A. H. S.

The following has been given in the Cultivator several times and we understand gives satisfaction when used; it is known as Government whitewash because first recommended by the Department of Agriculture. As it is quite elaborate we first say that the addition of a strong salt solution to the ordinary lime solution makes it a fairly good outdoor wash, but of course not equal to the following:

Take half a bushel of unslaked lime slack it with water, cover during the process to keep in steam, strain the liquid through a fine sieve or tsrainer and add to it a peck of salt previously dissolved in warm water, three pounds of ground rice boiled to a thin water and stirred in while hot, half a pound of powdered Spanish whiting and one pound clean glue previously dissolved by soaking in cold water and then hanging over a slow fire in a small pot hung within a larger one filled with water. Add five gallons hot water to the mixture, stir well, and let it stand for a few days, covered from dirt. It should be applied hot. for which purpose it can be kept in a kettle or a portable furnace. Coloring matter may be added as desired. For cream color add yellow ochre; pearl or lead, add lamp or ivory black; fawn, add proportionately four lbs. of umber to one pound of Indian red and one pound common lampblack; common stone color, add proportionately four pounds raw umber to two pounds lampblack. For interior work: Slake a peck of lime till it is thick and creamy. While it is hot mix with a pint of linseed oil and one-quarter pound of glue previously dissolved in water. Let the mixture stand several hours before applying it. A little lampblack dissolved in vinegar and mixed with whitewash gives a grayish tint, which may be preferable to pure white, a little umber gives fawn color and yellow ochre a cream tint. Very little coloring matter should be used, or the shade will be too dark.

The cheapest method is, perhaps, whitewash made as follows: 30 pounds of lime, 4 pounds of tallow and 5 pounds of salt; sufficient water to make flow well. Another method is to set a shake or any object on the south or southwest side of the tree, so that the trunk is protected from the afternoon sun, wrapping with straw, old paper, or other cheap wraps is also resorted to. The best of all, perhaps, is the Yucca Tree Protector, which with its wires in place ready for instant attaching to the tree makes a perfect protection which will rest in position as long as the tree needs it. Of course ultimately so prune your tree and shape the head that the protection will be given by the tree's own leaves.

Sunburn.

Kindly let me know through the columns of the cultivator the time of the year to protect the trees against sunburn, what varieties are the most suspectible and the best method to pursue, and oblige—A Subscriber.

The time of the year when a tree is most susceptible to sunburn is hard to say, though the summer with its greater heat doubtless does the greater damage. However, if the newly set tree, or an old tree be heavily pruned, so as to let the direct rays of the sun strike the trunk, great damage and posibly death to the tree will result. Under such conditions, nearly any tree is susceptible to injury and should be protected; walnuts, prunes and peaches especially require care.

Cream Separators, all sizes, all prices. O. J. Weber Co., 555-557 S. Los Angeles street, Los Angeles.

Mites on Horse.

We have a mare 6 years old, which has been troubled this last two months with an itching. She rubs her hair off until it bleeds. We have applied different washes which do not seem to do much good. She looks fairly well. Would chicken lice live on a horse?—W.

This mare in all probability has chicken mites. If so, smear all over with sulphur and lard. This will kill the lice. If after leaving this on three days she is not reneved,dilute 4 ounces of Encamphol in quart of water and apply daily.—W. J. Oliver, V. S.

CLEAN UP THE CITY

Horticultural Commissioner Dingle, of the Los Angeles County Board, sends out with the following warning to fruit dealers of the City of Los Angeles: "You are hereby notified that every person having citrus fruit for sale that is infected with either Purple, Greedy or Red Scales, will have the same destroyed and is liable to arrest and punishment."

The Commission is also actively engaged in clean up work around the suburbs of the City of Los Angeles, getting after the owners of trees in yards which in the past have never had any care and are infested with Purple or Red Scale, and insisting upon the clean-up of those places. To the end that there may be no excuse on the part of the property owner, the Board of Supervisors have supplied to the Commission fumigating outfits of sixteen tents which will be used in cleaning up these city orchards.

PACIFIC COAST NURSERYMEN.

President F. W. Power of the Pacific Coast Nurserymen's Association writes us that the next meeting of the association will be held at Salem Oregon, July 10th, 11th and 12th, in connection with a Cherry Fair under the auspices of the Marion County Horticultural Society, and there will be present the Commissioners of Horticulture from Washington and Oregon and we expect also the Commissioner of Horticulture from California.

The Pomona Institute will be held under the direction of Conductor Neff on June 28 and 29, begining Friday, June 28, at 1:30.

Veterinary Instruments, Black Leg and Anthrax Cure, Milk Fever Outfits. See O. J. Weber Co., 555-557 S. Los Angeles street, Los Angeles.

SERMONS BOILED DOWN.

The rightness of a thing does not depend on its wryness.

A man is not firm in faith because he is fossilized in mind.

The peroration of a sermon often prevents its application.

Most moral infection comes from apparently small vices.

Living in the past only puts the headlight on the rear platform.

A man is never happy until he has ceased to care whether he is or not.

One does not have to be crusty in nature to give a crust to the needy.

You cannot atone for stealing the bakery by giving away a few biscuits.

An honest laugh may have more religion in it than the most pious logic.

And now, fathers and mothers, a word to you. Strive earnestly to make home the best place on earth and farm life an honorable and profitable calling, so there will be little or no disposition to leave it for other occupations. Encourage the children by getting them interested in the work of the farm and home and be not afraid of allowing them to have something of their own. The children may become interested in the poultry business, that is nowhere rightly managed, becoming to be so profitable. They should have a corner in the garden and flower plats to care for and own. Get them interested in having everything about the home kept in the best of condition, something beautiful to look upon and a pleasure to own.—Hoard's Dairyman.

HOT WEATHER AHEAD.

How To Keep The Kitchen Cool And Comfortable in Mid-Summer.

Many a housewife is wondering how she will pass through the coming summer months with the stove she well knows will make the kitchen unbearably hot—to say nothing of the dirt, dust and ashes that will add to the discomfort.

There is a way out of it all—a way that not only lessens the work and keeps the kitchen cool, but that also reduces fuel expense. This convenience, comfort and economy is all effected by the New Perfection Wick Blue Flame Oil Cook-Stove, an oil stove so superior to other makes that it is fast replacing the coal and wood range, the old-fashioned oil stove, and in many cases the gas stove.

Anyone who has had to wait ten or fifteen minutes for the fire to get started will appreciate the New Perfection, which gives a strong working flame at moment of lighting. "Blue Flame" means the hottest and cleanest flame produced by any stove. The flame is always under immediate control and can be raised or lowered instantly. The convenience of this will be understood when it is considered that while the flame of one burner is boiling the kettle or roasting a large joint, that another can be reduced to simmering point—in this way enabling the housewife to cook a variety of dishes at one time.

Then the comfort of it. While the flame of the New Perfection is intensely hot, yet the heat is not thrown off into the kitchen because it is concentrated by blue-enameled chimneys.

On washing and ironing days the comfort and convenience of the New Perfection will be greatly apreciated. It gives best results in the least time, and does away with all coal and wood carrying and the many other disagreeable jobs that have to be done with other stoves. The New Perfection is made in three sizes, with one, two, and three burners, and is warranted to give full satisfaction.

Another home comfort is the Rayo Lamp, which produces a light of unusual brightness, yet soft and mellow—a light that will not hurt the eyes. It is highly ornamental and is warranted and makes a valuable and handsome addition to any home.

The New Perfection Wick Blue Flame Oil Cook-Stove and the Rayo Lamp are two real essentials to home comfort. Their easy operation, absolute safety and handsome appearance commend them wherever stoves and lamps are used.

Raise Every Chick

If every Chick hatched last season had reached maturity in 60 to 90 days—hardy, strong and vigorous—how much extra money would you NOW have in the bank? You could have SAVED these Chicks—every one—if you had used

Purina Poultry Feeds

—for one kind—Purina Chick Feed, is made on purpose to save the lives of little chicks, and make them grow like weeds. And it DOES IT. Brings up the highest percentage of every hatch EVERY TIME.

The other Purina Feeds MAKE EGGS—make your hens lay all the year 'round—make zero weather eggs EASY. They do this EVERY TIME, and with EVERY HEN, too. These may sound like "broad statements."

But don't take OUR WORD for it—try it—prove Purina Feeds yourself by feeding them to YOUR hens or chicks at OUR EXPENSE. If the RESULTS don't come, just write up the bag and write us, and we will return every penny of your money, and tell you what to do with the unused feed. You are not out a cent in making the trial, for we will supply you through your dealer or direct, FREIGHT PAID, and the feed used in testing will cost you nothing.

This is the Money Back line. Ask for particulars about our FREE TEST Plan. Write today—you can't afford to wait.

Four Great Occupations

The privileges and opportunities of the modern-day farmer are so ably set forth in an address made by Mr. J. P. Wise, manager of Elmwood Farm at Metuchen, N. J., before the graduating class of New Jersey College of Agriculture that the Cultivator deems it worth quoting liberally from. If for the Jerseyman the "only outlet which insures future prosperity lies along the path of knowledge, expert knowledge of the elements of farming," then for the California farmer with the peculiar conditions confronting him, great distance to market and other factors the same is doubly true. Besides, if the farmer would have the respect of other business men he must command it by becoming as educated as a class as those men are. As a matter of necessity, the respect of mankind will turn towards men who have the best developed minds. Mr. Wise says:

Four Great Occupations.

Of the four great occupations of mankind, agriculture, mining, manufacturing and commerce, the first, agriculture, was an old pursuit while the others were in their infancy. Yet today, looking at the four in any part of the earth, we see how the other three have been organized, systematized and their practice based upon fundamental laws. At the same time, it is true that the practice of farming, old as it is, has advanced but slowly, and even in this progressive country the farmers are laboriously and stubbornly true in their filial duty, farming as father used to farm.

Speak to a great majority of farmers of bacteria, the wonderful qualities of the clover family, or of green manuring and they look at you as if you were speaking in a foreign language.

All of which leads to this: The necessity of careful, intelligent farming, by trained men, with a full knowledge of what we are doing and why we are doing it. We can acquire this to some degree by careful reading of farm literature, close observation of otners successes, and best of all, from the agricultural college. Here the knowledge is given in a systematic form by highly efficient teachers.

How to Get Wise.

When we stop to consider what farming is and the knowledge underlying it, we readily see how senseless and how stupid any opposition to learned farming (if I may use the term) is. A farmer's stock of knowledge upon his subject must be what has been told him by word or books, or what he has observed.

John Jones has a banner crop of wheat or is growing an entirely new kind of plant, we hear. If we are intelligent, we will go over to see John Jones and find out all he knows about his success.

Book Farming.

Gradually, through instances of this kind, new knowledge about various things percolates, so to speak, through the community. Now the farming taught through books and the agricultural school is simply a compilation and digest of numberless farming experiences. Jones and his new crop is multiplied a million times. What father has told us has been multiplied a thousand times, proved or disproved.

What has happened in Europe and Asia is brought to our knowledge in America. What California, Colorado and Iowa are doing becomes part of our knowledge in New Jersey. The whole world is performing for us, in field and laboratory, and we have but to keep our minds open and be intelligent to profit from the successes and failures of agricultural mankind.

Must Know Many Things.

What a myriad of things the farmer should know and understand. He should be some sort of a geologist and understand the value of the soil, its formation and kinds. He should be a sort of a physicist and chemist, and so understand the beneficial action of sunshine and atmosphere and the conservation of rainfall.

He ought to know of the million of germ life working, tearing apart and making future farming possible for him, yet at the same time, he ought to know of those working against him, rendering his milk and dairy products a menace to human health.

The soil to him no longer should be a dull, inert mass, but should be something alive and energetic, anxious to break forth into harvest, and to do abundantly for the one who understands it and treats it kindly.

It is true in many cases agricultural science of today merely explains the well-known agricultural practice of yesterday, and that it does not take away the blindfolds of those who seek its mysteries and show to him a sure, shining path to success.

But the very fact of knowing that a thing should be done and why it should be done, the understanding of the law behind the practice gives a man new zest in his vocation. He becomes more able to handle emergencies. His brain is stimulated. He becomes a master of his farm.

Jerseymen Need Brains.

We farmers here in New Jersey have cause to use the full power of our brains. The West today, with naturally richer lands and less exhausted soils, competes successfully with us in our Eastern markets. It is easy to see that with decreasing freight rates, and they are sure to come, (perhaps government ownership), the competition will become stronger and fiercer and with other things being equal the battle must go to them.

To the New Jersey farmer the only outlet which insures future prosperity lies long the path of knowledge, expert knowledge of the elements of farming. Think of our incomparable markets. Knocking at our door are ten millions of people demanding fruit, vegetables, milk, cream, hay, fodders and grain. To hold, or even share, this market, we must improve our methods.

Should Try for Big Crops.

The New Jersey farmer, whether his proposition be market gardening, dairying or general farming—that is, raising the coarser crops, either for the markets or for home consumption—should push his crops to the limit. A certain maximum crop of potatoes or wheat can be raised from our land, the amount being limited chiefly by climatic conditions. Then his maximum crop should be our aim. The cost of soil preparation, the cultivation, the harvest is practically the same for a poor crop or a good crop. To insure the good crop, the use of manures and fertilizers is necessary. Therefore a complete knowledge of the kinds of fertilizers and soil and crop preferences must be acquird.

NEW ORCHARD CULTIVATOR

Household Department

MEMORIAL DAY.

THE thirtieth of May is set as a day when we as a nation pay tribute to our soldier dead. Services are held in every part of our land, and flags and flowers are placed upon the soldier's graves.

When our nation is enjoying peace and prosperity, it seems especially fitting that laurels should be bestowed upon those who rendered assistance in times of war. It is simply showing our appreciation of the bravery and self-cacrifice which helped to bring about our prosperity.

The graves of those who are buried among friends will be cared for, but hundred's of soldiers' graves are far away from friends, and are even unidentified—those should have especial attention from the hand of the nation.

The ranks of Union soldiers who follow to the cemeteries grow perceptibly less each year, and the step is not quick and elastic as it was. Would it not be appropriate for us on this day to also honor the living soldiers? They did not give their lives, but risked them, and many sacrificed health or personal prosperity. There is a beautiful little poem entitled "If I should Die Tonight" whose thought is that if the writer should die, many flowers would be brought and kind things would be said of her, but she thinks to herself how much more she would appreciate them if a few kind things were done and said while she is yet alive.

Celebrating a Merorial day develops patriotism, and strengthens the cords which bind us together as a nation. It is a regrettable fact, however, that some are not willing to celebrate a holiday which shall not be one of jollification; the day of mourning should not be used for games, sports and entertainments. It is a day which should be held at least in honor and respect.

In the beautiful month of May when the world abounds in flowers, it seems but just that each soldier's grave should be rembered with a wreath. It is, indeed, appropriate that the muffled drum should lead the step of those who place the flag and lay the flowers upon the graves of our nation's protectors.

In Remembrance

Again is heard the roll of drums,
Again the trumpets play,
In honor of the soldier dead;
And comrades come to lay
On each green mound a sign of love,
And speak again each name
That time nor change can ever blot
From the bright scroll of Fame!

And as each year its circle makes,
This day of memory comes,
And marching feet keep old-time step
To beat of rolling drums.
Around the graves where blossoms lie,
And soft young grasses creep,—
Where waves the Flag which cost so much
To gain—so much to keep!

But veterns few and fewer come
The fragrant wreaths to bring,
For one by one they join the ranks
Of those long slumbering.
But they too share the words of praise,
And share the wreath of bloom;
For in the Nation's memory
Each one finds welcome room!

A few years ago the United States Department of Agriculture started a plantation of osiers on its experimental farm at Arlington. It has been thriving, and recently a quantity of the willow wands, ready peeled and prepared, was sent to a manufacturer of willowware, who converted them into chairs, settees and other articles, that a blind basketmaker declared were better than those from the imported article.

"She let fall a few remarks——"

"Is that why she spoke in such broken tones?"—Baltimore American

BLOSSOMS FOR THE BRAVE.

We think of you as brave and true,
Grand Army of the Dead;
You lie 'neath sod and dew,
Grand Army of the Dead.
Thou who didst the nation save,
Here we come to deck thy grave,
Scattering blossoms on the brave
Grand Army of the Dead.

No more ye hear the cannon boom,
Grand Army of the Dead;
Your flag is floating o'er your tomb,
Grand Army of the Dead.
Here we come with flowers today,
Here our orisons we say;
Sleep ye here till Judgement Day,
Grand Army of the Dead.

Your bivouac is grassy knoll,
Grand Army of the Dead;
Eternal rest, your long parole,
Grand Army of the Dead.
Death-white lips, the blood-red hue,
Staining every blouse of blue,
Show the nation's debt to you,
Grand Army of the Dead.

Comrades, uncover! Make salute!
Grand Army of the Dead;
Sweet messenger, these flowers mute,
Grand Army of the Dead.
Precious blood, when valor dies;
Hallowed spot where patriot lies;
Gateway up to paradise;
Grand Army of the Dead.

FAMILY ANNIVERSARIES.

"Thanksgiving and Christmas, wedding days and birthdays, are occasions that should never be neglected in the life of the family," writes Margaret E. Sangster in Woman's Home Companion for June. "Even though the married children go far from the early home, living in widely separated neighborhoods, they should make an effort to get together at stated intervals, and so long as their parents live, the old home, with its dear memories, should draw them like a magnet to its hearth. Little cousins ought to know one another and be acquainted as brothers and sisters are. When long trips across the continent involve too great an expense or frequent visits, there is always the letter box on the street corner or the rural free delivery, and the post may be trusted to carry love messages safely from Maine to California, or around the circuit of the globe. How the mother at home watches for tidings from her married children, and how she grieves when for weeks and months she never receives a word and feels that she has dropped out of the daily lives of those for whom she toiled and saved years ago.

"Do you owe your mother a letter or a visit or a gift, you who are far away from her now? Do not let the sun go down until you pay that debt of love.

"Do not forget that although we may have many friends, we can have but one mother, and that no friend can be quite so intimate as she."

"Schwartz's Pattery Vas Took."

During the battle of Shiloh an officer hurriedly rode up to an aid and inquired for Grant. "That's the man, with the field glass," said the aid.

Wheeling his horse about the stranger rode furiously at the general and, touching his cap, addressed him thus:

"Sheneral, I vants to make one rebort—Schwartz's pattery is took."

"Ah!" said the general. "How was that?"

"Vell, you see, sheneral, der shecessionists flanked us, und der shecessionists come in der rear of us, und den Schwartz's pattery vas took."

"You, of course, spiked the guns."

"Vot!" exclaimed the Dutchman in astonishment. "Schpike dem guns! Schpike dem pran new guns? V'y, it would shpoil dem!"

"Well," said the general sharply, "what did you do?"

"Do? Py chimmeny, ve took dem pack again!"

SOME RECIPES.

Banana Pie.

Free enough bananas from skin and coarse threads to fill a cup when the pulp is pressed through a sieve or ricer. To the pulp add a beaten egg, one-half cupful of sugar, one cracker powdered fine, one-half teaspoonful of salt, one-third of a teaspoonful of cinnamon, two tablespoonfuls of molasses, one-third of a cupful of cream and one-half cupful of milk, mix thoroughly, and bake until firm in a pie-pan lined with pastry as for squash pie.—Woman's Home Companion.

Cherry Shortcake.

Make a soft dough of four cupfuls of sifted flour, two teaspoonfuls of baking-powder, one teaspoonful of salt and four teaspoonfuls of butter. Mix with milk. Cook in two layers, buttered. When brown, remove from the oven, butter again, spread the bottom layer with cherries that have been stoned and sweetened, put on the top crust, and cover with fruit. Serve with whipped cream.

Strawberry Shortcake.

Two cupfuls of flour, two teaspoonfuls of baking-powder, two tablespoonfuls of butter and a pinch of salt. Mix with milk, roll out in two layers, butter and bake. Spread with the berries, sprinkle with sugar, place the top layer on, butter, and cover with berries. Over this spread a layer of meringue made of the beaten whites of two eggs and three tablespoonfuls of sugar. Brown quickly, without cooking the fruit. Serve with whipped cream.—Woman's Home Companion.

HOMELY HINTS.

Pieces of rubber tubing slipped over the kitchen sink spigot will keep many a fine dish from being nicked.

If the bottom of the pan in which milk is being heated has been greased first with butter the milk will not burn.

Two ounces of boric acid crystals to a quart of water makes an excellent solution for burns. It is also a good antiseptic solution.

Milk taken hot or cold is fattening, but it should always be sipped, never swallowed hurriedly. To induce sleep, sip a cupful of hot milk before retiring.

To make paper and cloth fire proof, dip into a solution of alum, then throw over a line to dry. Test in the flame of a candle, and if a tendency to burn is shown, repeat the alum bath.

Apple, potato and most other stains can be removed from the hands by rubbing them with oatmeal mixed with lemon juice or vinegar. When the stain is quite removed wash with warm water and soap.

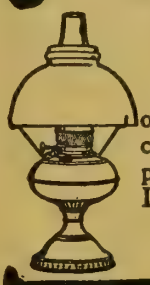
A Summer Vacation in Your Kitchen

Don't swelter this summer with the temperature at 110. Get a New Perfection Wick Blue Flame Oil Stove and have a cool kitchen. The

NEW PERFECTION

Wick Blue Flame Oil Cook-Stove

produces a working flame instantly. Blue flame means highly concentrated heat, no soot, no dirt. Oil is always at a maintained level, ensuring a uniform flame. Made in three sizes. Every stove warranted. If not at your dealer's write to our nearest agency for descriptive circular.



The **RayoLamp** is the best lamp for all-round household use. Made of brass throughout and beautifully nickeled. Perfectly constructed; absolutely safe; unexcelled in light-giving power; an ornament to any room. Every lamp warranted. If not at your dealer's write to our nearest agency.

Hopkins & Allen "WILD WEST" REVOLVER

POST-PAID BY MAIL

32 or 38 Calibre

A REVOLVER EVERY FARMER SHOULD OWN

6 Inch Blued Steel Barrel

Write for our Big New "Gun Guide and Galalogue" for 1907. It's free and the best and most interesting Firearm Catalogue published in America. Offers best prices.

HERE'S A REVOLVER THAT OUGHT TO BE IN THE POSSESSION OF EVERY FARMER IN THE COUNTRY. It is especially designed for the farmers use—long range shooting and extra thorough protection. With it you can get at the night prowler in barnyard or chicken lot without coming to close quarters with him, and the blued barrels keep the sights clear in the moonlight giving you double protection against the foe.

DESCRIPTION: This revolver is specially constructed for farmers use, of high-grade material throughout, **and is warranted to give extra good satisfaction. Barrel and cylinder** are made of best blued revolver steel, drop forged, with our popular improved quick twist rifling, which **increases velocity and improves trajectory. Cylinder** is supplied with ratchet stop and counter-sunk pinion giving rapidity of action and extraordinary accuracy. **Frame** is made of Blued Steel and all lock work of high-grade spring steel. **Hammer and Trigger** are made of fine drop forged steel, **case hardened**; hammer rebounds after firing—never resting on cartridge except at the instant of discharge. Revolver is **Double Action,** self-cocking with hard, checkered rubber handle, pistol shape, which fills the hand and gives an excellent grip. 32 Calibre, 6 shots, 38 Calibre, 5 shots. ALL IN ALL THIS REVOLVER IS EXTRA HIGH-GRADE FOR THE PRICE, AND FOR FARMERS USE IS SUPERIOR TO MANY OTHER REVOLVERS COSTING TWICE THE MONEY.

IF YOU SHOULD NOT FIND THE "WILD WEST" REVOLVER AT NEAREST HARDWARE STORE SEND $3.50 DIRECT TO US, AND WE WILL FORWARD IT AT ONCE, POST-PAID BY MAIL WITH AN ABSOLUTE GUARANTEE OF SATISFACTION, OR IMMEDIATE REFUND OF MONEY. Same Revolver, 4½ in. barrel, $3.25, 2½ in. barrel, $3.00. Mention Calibre wanted when ordering.—Write us at once.

The Produce Markets

Los Angeles Markets

LOS ANGELES, May 29, 1907.—Most products are holding firm at but slightly changed quotations from last week. There is a slight holding off on the part of some dealers until the first of the month which makes the demand not so heavy as a week ago

Butter.

Receipts of butter yesterday were heavy. The high prices which went into effect at the close of last week attracted the heavier supply, most of which came by boat from the north. Notwithstanding this increase dealers report they are cleaning up their allotments without difficulty and at times are even drawing a little Eastern from storage.

Citrus Market

LOS ANGELES, May 29, 1907.

The closing of the navel season finds the orange growers wearing the "smile that won't come off," and while the past three or four weeks haven't hit quite the high points of the earlier season, there is nothing in it discouraging.

At this writing, the consumption is heavy and a good tone prevails, in fact, the market may be said to be strong. There are many "large offs" which cause a little embarrassment in hunting a market which will absorb them at a winning price; but thus far, fair results are obtained even with them.

Orchardists have not complained of puffs or drops, or at least those evils are reduced to a minimum. In that respect this is nearly a model season.

Soon Finished.

Navels will soon be finished. Valencias are going out up to this time under special orders only. Seedlings and Sweets command fair attention.

As to the future, information from all over the country leads to the belief that there will be a good market for all late fruits. It is a fact that the East has produced no early fruit of any kind. The strawberry crop is practically a failure everywhere and the very uncertain weather in the East, hot a few days and then cold, has virtually ruined the crop. The eastern cherry crop is also a failure and the only fruit they will have in any amount is California oranges. Pineapples are high, exceedingly high and scarce. Bananas are also high, but this fruit is in a class by itself and effects oranges only in a small degree.

Lemons.

Lemons bravely hold up under the most adverse conditions. The early hot weather of the East when California could get no cars to forward its fruit caused the great influx of "foreigns," much to their sorrow, for the later cold weather put prices out of joint, so great quantities are on the New York docks at this writing. However, Californias have the pull with the consumer who knows their superior qualities and often refuses the "just as good as" foreigns, so that Californias have at times commanded a dollar advance over the Mediterranean fruit.

Grape Fruit.

Grape Fruit is now receiving fair treatment and the small quantity now in hand will clean up at fair prices.

Shipments.

Shipments to date aggregate 20,698 cars, of which 1966 were lemons. To same date last season 20,891, of which 2311 were lemons.

NEW YORK, May 27.—The market is very strong and higher on bulk offerings. The very ordinary quality in bad order. Raining. Thirty-four carloads oranges sold.

The Irrigation of Orange Trees

THERE are three methods of irrigation in California, viz., the furrow, the basin and the zig-zag systems. Our illustration gives a clear idea of the practical working the furrow. As the name implies, the furrow system consists of several furrows plowed between the rows of trees, and down these the water is allowed to flow gradually until the ground is thoroughly saturated. In furrow irrigation the water should be allowed to run very slowly in order to percolate through the soil to a considerable depth and at the same time prevent its washing down and leaching out the ground.

The basin system consists in each tree being basined, an operation usually performed by a plow or what is known as a blocker or ridger, which consists of a V-shaped implement made of wood and iron or iron alone. This throws up a ridge or embankment of earth around each tree, which is allowed to fill with water from the main furrow, once or twice. In this way the whole grove is treated, each basin being filled independently from the main furrow between the rows of trees which tap your main supply ditch.

The zig-zag system is an improvement on the basin system, and consists in the orchard being first cross-furrowed, then ridged lengthwise as indicated. Its chief advantages consist in obviating a baking of the soil by not covering the entire surface of the ground with water, thus affording sufficient dry earth to make a mulch when cultivated over the entire irrigated surface (an operation which can be done sooner after irrigation than in the basin system.) This leaves the soil friable and at the same time conserves the moisture in the ground, which obviously is a great advantage over the basin system.

Irrigation on rolling or hilly ground is of itself quite an art, and is practiced by running furrows on the contour so as to guide the water without overflowing and thus flooding the soil. The artificial application of water to side hill orchards is only feasible by the furrow system in the manner indicated in the illustration.

It is an axiom among fruit growers in Southern California to first find your water and then look for a good piece of land on which to put it. This illustrates the importance of a reliable supply of water for irrigation purposes when planting and cultivating an orange grove. Indeed, in the climate of California, portions of Old Mexico and far-off Australia and South Africa, citrus culture is only feasible where there is an available water supply with which to carry the trees over the dry season.—From "Citrus Fruits," by R. M. Teague.

Citrus Fruit Growing in California

A Magnificent Publication in Which is a Great Fund of Information on Citrus Fruits

The Washington Navel

"The Most Valuable Orange Known," is What Teague's "Citrus Fruits" Calls the Washington Navel

THE ENTERPRISE and up-to-dateness of California tree growers is proverbial. The great fruit interests of the State have brought into being many extensive nurseries and these are largely managed by shrewd men with modern ideas of business.

One of the largest of these, and with best of reputation, is the San Dimas Citrus Nurseries owned by R. M. Teague. This is mentioned at this time because of the recent issue of a catalogue, or more properly a Treatise on Citrus Fruits, which is such a remarkably fine publication of its kind that it is well worth this space. It is a 48-page, 10x12-inch book on fine coated book paper and filled with illustrations showing nearly every feature of citrus culture from the starting of the seed to packing of fruit, or to be more exact, we quote the title page:

"A preachment on their culture from the seed to the full bearing orchard, describing methods of propagating, budding, cultivating, fertilizing, irrigating, packing and shipping."

In the matter of fruit packing there is a series of plates showing the various standard packs, both of oranges and lemons.

A Great Industry.

Regarding the importance of the industry, the preface of the book says:

"No one industry has done more to individualize Southern California than the growing of citrus fruits, of which she now produces larger quantities than all of the remainder of the United States combined. And this is not by chance, nor because the industry has found the greatest investments of capital, but because the soils and climates of this section are peculiarly to the liking of the orange and the lemon tree. To show how thoroughly this fact has become recognized in the markets of the world, it is only necessary to note the onward trend of the industry since it assumed national importance in the annals of trade and the statistical division of the National Department of Agriculture. The figures tell the story more forcibly than mere words."

Then is given a table of shipments showing the increase of Southern California shipments from 4016 cars in 1891-2 up to the banner year of 1904-5 with its great output of 28,000 cars, with a money value of nineteen millions.

The great importance of the industry is given as the reason for issuing so an elaborate treatise as Mr. Teague has sent out. The varieties of citrus fruits are not only fully described but illustrated with remarkably fine half-tones. One peculiar thing about the book, is that while it is issued primarily—we assume so at least—to sell nursery orange trees yet, occupying a considerable space, freely illustrated, are full instructions on growing and budding nursery stock. In other words, he is giving his whole trade away. In that respect he is like a certain great sculptor who was approached by an anxious mother who hoped for her son the fame of a great sculptor. She asked the secret of great success and was answered: "It is simple indeed. Take a block of marble and with a chisel knock off all the marble which you do not want left for the statue."

The growing of a young orange tree is still more simple and Teague gives all the details, but we assume that he will continue to find market for his magnificent stock for many years to come for, coupled with his fine goods, is courteous and thoroughly honorable treatment.

Mr. Teague is an honor to California nursery business.

Deciduous Fruit Culture

CARE OF VINEYARD.

NOW is the critical time of the year for the coming grape crop. Its arch enemies, the mildews begin their work. There is, however, but one of the mildews known in this State, that being the powdery mildew, This is bad enough and if not taken in time will destroy the whole crop and injure the vines besides. It attacks the fruit, foliage and growing canes.

The locality in which the vineyard is makes a difference in the severity of the attack. Interior valleys are more free from it than those near the coast or within the influence of it. We are told that in the desert regions powdery mildew does not exist and sulphuring is not necessary.

Powdery mildew is usually seen first, about the time the blossoms open and can be distinguished by light-colored patches on the leaves and tender growth. The fungus does not enter the tissues deeper than the outer layer of cells and therefore can be destroyed or checked at any time during the growing season. The gas or fumes given off during a hot day will kill all the mildew that it comes in contact with.

If the mildew is bad, it sometimes affects the setting of the grapes. Sulphur will also affect the setting when the temperature gets above 100 degrees, but this cannot be ordinarily expected as such temperatures rarely occuring so early in the season. Such temperature will destroy most of the fungus in exposed places; Bioletti says that a few degrees above 100 will kill it.

The proper time to sulphur is about blooming time. Under ordinary conditions, sulphured vines set the fruit better than when no sulphuring is done. If there are signs of mildew after the grapes have set, sulphur again and it is not likely that it will be necessary to do so again. Some of the late ripening varieties are affected during a damp period in the fall before the grapes turn in color. After the grapes turn in color, there is no further trouble. Sulphur will do no good unless the temperature rises to about 80 degrees. If the sulphur is evenly distributed, such a temperature will destroy the mildew. If no damp weather occurs during the remainder of the season, there will be no further need of another application if a thorough job is done.

Vines in the shade of trees or a building are more susceptible to mildew than those in the vineyard form. Trellised grapes are more apt to be bothered as are also vines with a dense foliage. Varieties vary in this respect and this is mainly the reason why some varieties are more susceptible than others. The fact that this mildew thrives best when protected from the influence of the sun, makes the difference and also allows the grower to make the vine less liable to attack by judicious thinning of the new growth. Sulphuring is, however, the most economical manner of combating it and applying with a blowing machine is the best method. These machines may be had at any of the seed houses. Sublimed sulphur is the best as it is the finest in grain and pound for pound has more exposed surface than any that is ground, giving the air a chance to send off the fumes more rapidly.

No man finds himself until he is willing to be lost.

SOME MISNAMED CALIFORNIA GRAPES.

All of the common grapes of California have been introduced from some part of the Mediterranean region where they have been growing for hundreds or thousands of years but most of them have been given incorrect names here.

This renaming has been due in some cases to a mixing of labels, in others to incorrect guesses of Europeans who thought they recognized the vines of their native soil, and in still others to the inventive genius of the first distributors of the varieties, who chose the name which they thought most likely to attract customers for their grapes or cuttings.

Some of these new names belong to other varieties and make our nomenclature confusing and misleading. The true Golden Chasselas, for example, is a very different grape from that which goes under that name in most vineyards of California. This "(Napa) Golden Chasselas" is the Palomino, the chief sherry grape of Southern Spain, much grown also in South Africa under the inappropriate misnomer of "White French." The real Chasselas, a much inferior grape for our conditions, is the variety known in Sonoma by its German name of Gutedel.

Another substitution of a similar kind is that of Feher Szagos. This name, which means "aromatic grape," is applied in Hungary to large table Muscats, and is quite inappropriate for our neutral flavored grape whose proper name is unknown. The Zinfandel and Burger are not the grapes known by those names in Europe and their identity has never been determined.

The name Flame Tokay was also an unfortunate choice. Tokai is the district which produces the finest wines in Hungary which are known in commerce under the name of the district. There is no grape of this name, and the variety from which the wine is made, the Furmint, is white, juicy and totally unlike our principal shipping grape.

Our Flame Tokay is probably the Algerian grape Amar bou Amar (Red Father of Red). The description of this variety fits ours exactly and some vines imported by the University, though they have not fruited yet, show identical foliage.

The Seedless Sultana is a similar case. This is not the grape from which the Sultana raisins of commerce are made. It is probably the Kechmish of Turkey.

Another of our most widely grown varieties of the Sultanina, which had lost its euphonious name and was dubbed Thompson's Seedless. It is certainly desirable to restore its true name and it should not be difficult with the help of the late correct labeling legislature.

The origin of the Mission is still an unsolved riddle. The vine closely resembles the Monica (Monk's grape)) of Sardinia, but is not identical with that variety as introduced in the University collection. It may be simply a variation of it due to centuries of unconscious cutting selection.

Our Cornichon is the Malakoff Isjum (Corporal's grape) of Turkey and our Malaga probably the Panse of Southern France.

What our Emporer, Verdal and West's White Prolific are remains undetermined.

Don't Push

The horse can draw the load without help, if you reduce friction to almost nothing by applying

Mica Axle Grease

to the wheels. No other lubricant ever made wears so long and saves so much horse power. Next time try MICA AXLE GREASE.

Malaga.... .... Panse?

Emporer, West's White Prolific, California Black Malvoisié, Zinfandel, Burger and Feher Szagos are still undetermined.—Frederic T. Bioletti, Berkeley, May 27, 1907.

BUDDING OLD GRAPE VINES.

Now is the time to bud over old grape vines. This is not grafting, as the season is too far advanced for that. The process is known as herbaceous budding. That is, budding in the succulent wood.

The work is done when the young growth is so far advanced as to have fiber enough to allow the branch to bend slightly without snapping. The buds are selected from buds which have the leaves nearly developed. The bud is inserted in a new cane by making a slit lengthwise with the cane, but do not make a cross cut in the slit. If it is done in the right place, the bark will bulge away from the wood when the cane is bent with the fingers. Place the bud which is cut in the ordinary way under the bark and when the branch is released it will draw the bark tightly down onto the bud, making it fit closely against the cambium layer. Wrap with a piece of cotton cloth cut in narrow strips. The leaf that grows at he base of the bud should not be removed entirely. Cut it so that a piece about the size of a quarter of a dollar will remain. Insert the bud with the leaf stem and that much of the leaf. If the bud takes the leaf stalk will remain green and will ripen and separate easily from the bud. If it does not grow, the leaf stalk will dry up with the bud. The cloth bands should be removed before they bind the canes. These buds had better be allowed to remain dormant till the following pruning season. At this time, make the cut one bud above the inserted one. Very often the last bud dies or gets broken and the long end will afford protection. After the bud is well started, the stock can be cut back to the bud.

MANURES AND SOILS.

Soils breathe quite readily as animals and this breathing is quite as essential to the fertility of the soil as the breath is to the life of the individual. In other words, in all soils in proper cultivation there is a movement of air both downwards and upwards and this air is quite as essential to the life of the plant as it is to the life of the animal.

The forces which cause this soil breathing are various. As the pressure of the air upon the surface of the earth is about fourteen pounds to the square inch, it can readily be seen that the spaces between the soil grains that are not filled with water are necessarily filled with air under normal conditions. The weight of the air varies with the changes in temperature of day and night. Hence the pressure varies, which promotes soil breathing.

When the hot sun beats down upon the field so that you can see wavelets of air rising, it necessarily follows that there must be an upward movement from the air in the soil as well. When night comes and the atmosphere cools down, there is correspondingly downward movement.

Then, again, there is a marked difference in the weight of the atmosphere at different periods. Any one who will examine the weather chart will see that the barometer sometimes rises to 30.2, which means that the weight of the air is equal to a column of mercury 30.2 inches deep. At other times it runs down to a little over 29, a difference of 3 per cent. in the weight of the atmosphere. This, again, promotes soil breathing.

Then, again, the winds as they smite the earth with the air tend to promote soil breathing. Drainage also promotes soil breathing, and in the most effective way. When you dig a ditch through a piece of very wet land you find the water rushing from the bottom and from the sides. These lands have not produced good crops of our ordinary grasses simply because the air upon which they depend could not find access to their roots. As the water passes out it leaves air spaces, which are promptly filled by reason of the pressure of the atmosphere upon the surface, thus supplying the roots of the plants with the life-giving oxygen. When the tile is laid and there is no water in the drain, air necessarily enters, comes in contact with the soil and makes the drainage much more perfect. This accounts for the fact that it is possible to drain land that has very little fall. The pressure of the atmosphere forces the water out into the tile and outward.

What hinders soil breathings? The most effective hindrance to soil breathing is the formation of a crust on the surface. It does not wholly prevent it, or else plants could not live at all, but it does prevent free soil breathing and accounts for the delicate condition of plants of any kind when a crust has once been allowed to form upon the surface. This lack of thrift is not wholly due to the lack of air, but when a crust is formed and connection between the water below and the air is complete; hence soils dry out rapidly and plants suffer from the lack of a sufficient supply of both air and water.

If the farmer wishes to have a thrifty growth of any kind of plants he must by every means possible prevent the forming of crusts, not merely by breaking up the crust when it has formed, but by keeping his soil so well supplied with humus that a crust does not form readily.

On the other hand, the dust mulch favors soil breathing as well as the conservation of moisture. This explains why a well-cultivated cornfield produces such a remarkable growth, while the poorly cultivated field on the same land produces only from half to two-thirds of a crop. These are some of the simple things which every farmer should understand and upon which the prosperity of himself and his family depends to a greater extent than he knows.

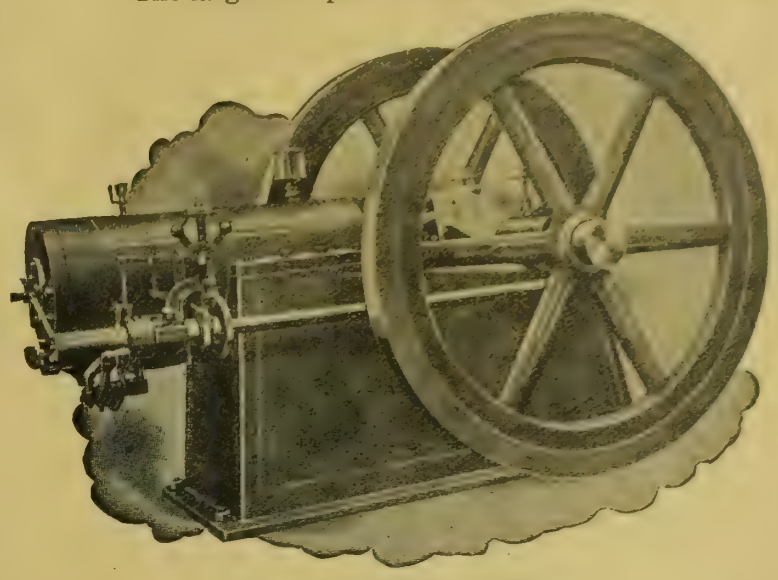
The New York State Grangers did one thing that the farmers all over the country will have to do sooner or later; and that is, sound a note of warning in the matter of road making. In some places where the state has undertaken the construction of the public highways, great political machines have grown up that are fairly robbing the people. Good roads are a blessing, but they ought to be built so that they will not entail a grievous burden of taxation upon us and our children. —The Ranch.

Columbus Engines

MADE BY

Columbus Machine Co., Columbus, Ohio

Have stood the test sixteen years.
The largest output in the United States



Standard Horizontal, 4 to 60 H. P.

Read what this man says about Columbus Engines:

Greenleaf-Compton Company, Tropico, Cal., 4-3-07.
121 So. Los Angeles St., Los Angeles, Cal.

Gentlemen—For about four years, I have used a Columbus engine of ten (10) horse power; which has been running a 3½ Vertical pump and pumping about 35 inches water with a 90 foot lift, and when the time came to buy a new pumping plant for my ranch near Anaheim where we we shall need water for about 200 acres, I decided to have a 60-horse Columbus engine installed, and placed the order with you because I expect to havea pumpimg plant that cannot be excelled.

Respectfully, E. B. BARY.

This 10-horse engine is pulling 13½ horse power. We are installing a 60-horse plant for Mr. Bary, 3½ miles north of Anaheim. Come in and let us demonstrate the simplicity of Columbus Engines.

Clean Skimming Means Good Living

The hog trough is no place to put butter.

Wide awake farmers want the cream separator that skims the cleanest. It means more profit—better living. That separator is the Sharples Dairy Tubular—the separator that's different.

Sharples Dairy Tubulars have twice the skimming force of any other

separators—skim twice as clean.

Prof. J. L. Thomas, instructor in dairying at the agricultural college of one of the greatest states in the Union, says: "I have just completed a test of your separator. The skimming is the closest I have ever seen—just a trace of fat. I believe the loss to be no greater than one thousandth of one per cent."

That is one reason why you should insist upon having the Tubular. Tubulars are different, in every way, from other separators, and every difference is to your advantage. Write for catalog S- 260 and valuable free book, "Business Dairying."

CORN.

WHERE corn is grown year after year, it pays well to have proper tools to plant and harvest the crop. Handwork is too expensive and men to unreliable to be put on to long-drawn-out work. The price of labor in California has grown in great leaps and bounds until today it is out of all reason. Only special crops such as oranges, grapes, melons and a few others are able to stand the heavy advance. Many farmers are growing melons to meet the expense of harvesting the hay crops that they must have to feed the horses. The hay crop promises to be short as it cost too much to plant last fall. These conditions are largely caused by the heavy draft of San Francisco on the farmers for horses, wagons and men. I know men that usually have twenty or thirty horses, and plow for their neighbors, that this year have had all their force in San Francisco working for wages; wages that would the winter before have bought the outfits in a couple of months. These are the reflexes of conditions that will not last long but are trying at present. The men at present, that had any glimmering of a knowledge of building craft, have been unionized and are in San Francisco working for seven dollars a day. At least so they claim. Some, however, are fooled. We had one boy leave on a promise of eight dollars a day as stationary engineer; in a month's time he was back running on an ice wagon at $50 a month and not "found," while on the ranch he had forty and found. Today we have had to cut up the big teams and can do little work, not even hauling, with more than a span of animals as four-horse drivers are not to be had. Only the older horses can be trusted in the incompetent hands; horses that are wise enough to take care of themselves and of the driver to.

Tools Needed.

The lister with a drill attachment is an ideal tool for California. The land is well cultivated, then furrowed and the lister puts the corn into the bottom of the furrow and covers it deep enough to make it start to grow quickly. In California it pays well to soak the corn over night as the water helps it start quickly. After the corn is up the cultivators begin to crowd a little dirt each time they run into the furrow. Every observer in a corn field must have noticed the roots that start from the stalk up to the first joint? These abort and remain dormant as they do not, under usual conditions reach the moist, cool earth to take up their natural life. The earth that the cultivators push against the stalks is warmed, sunned earth that lies lightly and these roots penetrate it and start to feed the growing corn plant.

The corn is given a double rooting system and the lowest ones are deep down where it is cool and moist, while the upper ones are where the sun is hot and the air penetrates freely. How do I know this? By personal observation. After the corn is cut, a deep furrow is run along side of the roots, another under the roots turns them out and the conditions can be observed. The corn roots shows a double and sometimes tripple series of roots coming from the stalk, when carefully dug out it is a mass of fibre four feet in circumference and two to three fet deep. Sometimes at he end of the rows the corn is shallow sown, this corn never makes the fine growth that the other does and shows when plowed up a weak root, all on the surface.

Irrigation.

Deeply planted corn with plenty of cultivation will often make a fair crop without irrigation. The amount of humus has much to do with retaining of moisture in the soil. This is a question out of my line as Stock and Dairy writer, but none the less I feel it is a matter that every grower of crops should think about. Corn well watered at tasselling time should produce abundantly of leaves and ears. The use of irrigating water is greatly abused around Fresno. The soil is crying out for humus to hold moisture; not for water directly applied. I know a fine vineyard that the original owner went to the expense of underdraining the land. The soil is naturally rather devoid of humus and settles down without air. Now if a quantity of stable manure, or straw, or cover crops had been planted this land would have grown richer and better each year. Instead of that the owner and foreman are constantly complaining that the ditchs (formerly in use only a few weeks) are not big enough. Water has been poured on the soil which grows dryer and dryer, commercial fertilizers have been put on, the soil is compact, and hard, for it has no air. The water carries a little air into it, but if the water should fail altogether for a year this place would die out badly. It is saved from a rise of alkali by the under draining, or else it would have gone out altogether. Now it is being leached out of fertility until in places the soil looks like sand that has been washed and re-washed for a filtering plant, so lifeless has it become.

Planting the Corn.

On moist land that has been well plowed and cross cultivated until it is in good neart, the lister can be well combined with the drill or planter and two rows listed at once. By using a double mould board the corn can be put into a shallow furrow with the planter. The reason for planting in the furrow is that if the grain of corn is placed more than four inches under ground, it does not come up strong and vigorous. The tiny plant depends on the food stored up in the grain to live on until the root system has developed and the plant becomes established as an individual; then by putting a little more dirt around it, the plant throws out more and more roots until we have obtained the object sought, of making corn a deep rooting plant without checking its vitality. Corn, or indeed any of the annual crops must never receive a check in their growth if good results are to be secured at harvest time.

Distance Apart.

If the corn is for soiling the rows are four feet apart, the corn in the rows is usually six inches apart. When grown for the ears every two feet apart in the rows seems about right. We find it pays to go over a field by hand and replant any missing hills, two weeks after the first planting. Keep the cultivation up and when it is necessary to turn the water on the corn, run a furrow between every other row and irrigate in the furrow to a point of saturation and then as soon as possible throw the earth into the furrow to keep the water from evaporating. Do not leave the furrow to become crusty and crack, for that will draw off more water from the subsoil than in all probability has been put on it. In the corn field this year I intend to sow field peas and oats and let them come up as they will. This will give, we nope, some early green stuff for the cows that can be cut later for the silo. In cultivating corn after it has started to grow shallow running tools should be used that will not cut the roots badly. When the plow has to be used it comes only into every other furrow, that cuts only a quarter of the surface roots. A wide cultivator with four horses abreast taking two rows at a time is a labor saving tool. These are set with the teeth shallow. The man rides and can see the row of corn he is over as it passes under the pole between the spans of horses. Another form of riding cultivator has come into use that uses three horses abreast. This requires more skill to use as the men get mixed and frequently go over the same or rather over a portion, say one-third of the ground a second time. The four-horse machine can easily handle twelve acres a day, usually three cultivatings is all that there is time to give them corn before it grows too tall. The ground is then shaded and the need of saving the moisture from the sun action has passed. As long as the ground is exposed to the sun, if it is not frequently stirred, it forms small ducts or air passages in to the ground and moisture is evaporated rapidly and dispersed.

TO FEED WITH ALFALFA.

In answer to a California enquirer as to a feed to give with alfalfa to balance the ration, Hoard's Dairyman says:

It is seldom possible to suggest a "best dairy ration." In fact, no one knows what combination of feeds will secure the most profitable results at the pail and, at the same time, insure the continued usefulness of the cow as a breeder and milk producer.

It is desirable to have some succulent feed for cows throughout the entire year, either from pasture, silage, roots or soiling. If for any considerable time such feed is not obtainable, we unhesitatingly advise feeding a moderate amount—two pounds or less per day—of linseed oil meal or cocoanut meal.

Alfalfa hay being rich in protein and low in carbohydrates and fat, does not make a well-balanced ration. Neither is it practicable for a cow to eat enough of it to furnish the nutriment required for maintenance and the production of a liberal amount of milk.

For example, a cow weighing 1000 pounds and yielding 25 pounds of 5 per cent. milk requires, at least, about 2 pounds of digestible protein, 13 lbs. of digestible carbohydrates and one-half pound digestible fat. There can be some interchange of these elements, surplus protein, for instance, taking the place of deficient carbohydrates.

Experience has shown that 20 pounds of dry forage is about the limit that a cow can eat in one day with profit. If called upon to eat more, the extra energy required to masticate and digest the excess detracts very materially from its productive value. Now, in 20 pounds of alfalfa hay, of average quality, there is 2.2 pounds digestible protein, which is ample for the 25 pounds of milk, as above, but only 8 pounds of carbohydrates and one-fourth pound fat. To supply the deficiency in these elements there is nothing that is quite equal to corn. But ground corn is too concentrated for either safe or profitable feeding. It must be diluted with some more bulky material, such as bran or chaffed hay. So, in this case, instead of feeding the ground corn by itself, cut some of the alfalfa hay quite fine and mix it with the ground corn, in the proportion, say, of pound for pound.

While we have had no personal experience with silage made from alfalfa and corn, we are firmly convinced that such a combination would be entirely practicable provided both crops were simutaneously in proper condition for harvesting. If not, they should be put in separate silos and silage taken from each daily. But it should not be forgotten that silage alone does not make a satisfactory ration. They need some dry fodder—nothing better than alfalfa hay—and some grain, preferably corn or barley.

The number of cattle on the Island of Guernsey is estimated to be 4000 to 5000 and, if this is true, only about 50 per cent. to 60 per cent. are registered, for 7000 females have been registered and much more than half of them are dead or have been sold. In driving over the island you would see many fine cows in a field and stopping to inquire would find they were not recorded.

Cream Separators, all sizes, all prices. O. J. Weber Co., 555-557 S. Los Angeles street, Los Angeles.

THE HOLSTEIN.

Here is an appreciative little sermon on the worth of the Holstein-Fresian by its warmest friend, the Holstein-Fresian Register. The other dairy breeds have some warm friends; let them speak up:

The intelligent dairyman, who desires and intends to establish a milk herd, will study the dairy breeds from all sides and from all points of view. Such a man will find, if he be liberal-minded as well as intelligent, if facts of achievement and truths of record appeal to him strongly and normally, that every element in the problem before him points in solution to the Holstein-Fresian breed as the breed he should adopt. The commercial feature of milk production drives straight to the Holstein-Fresian conclusion. The Black-and-Whites can make more milk, and therefore cheaper milk, than any other cows. They are, practically, the only cows in commission whose cost of making milk has been low enough to enable producers to sell at a profit at the liquid-market prices that have prevailed in the Middle States and the New England States during the past fifteen years. The chemical and dietic features of milk point Holstein-Friesian ward. No other cows produce milk so nearly identical in composition with human milk. Consequently no other cows are comparable with the Black-and-White producers of food for human beings. This quality is recognized by the scientific food experts of Europe. The butterfat in the Holstein-Fresian milk is exceedingly small in grain and so perfectly emulsified in the whole milk that it answers perfectly every demand conceivable for a perfect article of food. The general utility element will lead to the Holstein-Fresian conclusion. After the great-yielding Black-and-White cow has made yearly profits for her owner, and has reached the retiring age, she is not a worthless asset. She is still capable of making a very profitable windup of her long and profitable existence. She can be fattened as well as though she were to the beef-cow-manner born, and her giant carcass will furnish meat that will top the market prices. The consideration of prolificacy will carry the investigator to the Holstein-Fresian conclusion. He will learn that these cows are unequaled for breeding, for bearing and for rearing their offspring. The question of quality in cheese and butter will solve itself along the Holstein-Fresian line, and with the quality will go the quantity. There is no essential in the milk problem that does not point Holstein-Friesianward. Because this is indisputably true, it is certain that the breed will grow in favor with all the really progressive producers of milk.

MUTTON CHOPS.

Save the bean pods and give them to the sheep.

The forage ration should preferably be bright, clear hay.

If the sheep are not in good flesh give them about two gills each of grain

Protect heavy wooled sheep from cold rains. The weight of the water will sometimes prevent the sheep from rising.

Make the sheep tame by kindness. They will do better for it. Keep away the dogs; bells on every fifth sheep will do it.—Farm Journal.

The Ornamental Garden

THIS MONTH.

THIS is a good month to watch things grow. To grow requires water, air, warmth. The warmth will doubtless be at our command. The air likewise, at least as to the tops of the plants, but bear in mind that the roots, or, at least, the best soil conditions at the roots, require air. Air cannot go to the roots through a baked or hardened soil. A well loosened and cultivated soil admits air and thrift of plant results. Don't imagine for a moment that keeping down weeds is the sole advantage of cultivation.

If the above be true, then the constant sprinkling on the surface of the ground about the plant, with never a loosening of the soil, is objectionable. Therefore, when you wet the ground about a plant, soak it. Then, spade and rake and hoe and, rake some more. Then, later, don't be in too big a hurry, but when it needs it soak it again. A little fertilizer added, the keeping off of pests and other requirements also have to be met, but results justify it.

Above all, this is a good month to remember that old adage, "tillage is manure."

Keep the lawn well in hand. Touch it up with a little well-rotted manure; say, a couple of inches deep, well washed into the soil with the hose. Then after two or three days rake off the surplus so that no injury occurs by smothering out the grass. Or a light application of bone meal is fine.

Trim edgings of borders and hedges. Dahlias and Gladioli may still be planted. Sow Eucalyptus and Cypress seeds for winter planting.

It is also a good plan to "slip" a few geraniums and put in pots for ornamenting the front porch. A geranium makes a beautiful house plant. They're so common in California that we are too prone to regard them almost as weeds. But the writer has one that has caused more favorable comment than a five dollar kentia, and yet all it cost was a little care in "slipping" a "Gen. Grant" geranium and changing from pot to pot until now it is a beautiful specimen of plant with a wealth of gorgeous red.

THE POPULAR WATSONIAS.

It is doubtful if South Africa has ever sent out a stronger candidate for public favor than the White Watsonia; certainly not in the long list of "Cape bulbs." Other species, ranging in color from rose-pink to scarlet, are sparingly grown, but the White Watsonia (W. O'Brieni) is more in demand at present than any other bulb.

The botanical difference between Watsonia and gladiolus are very sligth, and it might well be termed a white species of the latter; but, horticulturally, it is of greater value than any gladiolus in the market.

One of the strong points lies in the purity of its color; one dealer in England advertises it as "the whitest flower on earth." Another point of excellence is its long period of bloom. It is what florists call a "laster," for not only is it a good keeper after being cut, but a bed which came into bloom for Easter cutting is still covered with blossoms, though nearing the end. The flowers are often three inches across and are more nearly bell-shaped than the usual gladiolus. From a good, strong bulb there will often grow a branched spike five or six feet high, containing nearly two hundred flowers. These bulbs seem to thrive equally as well as in California as is the case in their native home, and with the strong demand coming from all quarters of the globe, it is likely that this State will lead in their production. It is a flower that should be found in all our gardens for they need little care and increase rapidly so that from a modest beginning one may, in a few years, have more flowers than could well be used in a single home. These bulbs are also sold under the trade name of Watsonia ardernei, but they are one and the same species, though doubtless there may be found two or more of what growers call different "strains" of the same species. Get the white for your garden, no matter what name is attached.

COOPERIAS.

Cooperias are interesting bulbous plants growing in New Mexico and Texas. They are of the amaryllis family and are a small genus of only two species, C. Drummondii and C. Pedunculata. Botanically they are separated from the zephyr flowers only by some small distinctions in their anthers and some difference in the character of their leaves. From a garden point of view the chief distinction is that the cooperias known as the giant fairy lilies and evening stars are night flowering, while the zephyr-anthes prefer the more conventional daylight. The C. Pedunculata has the larger and more attractive flowers, which are two inches in diameter, white and rose tinged on reverse petals. C. Drummondii are of same coloring but smaller, while the variety chlorosolen has greenish tints. The bulbs of these two families seem to occur in swampy or wet ground, although they flourish in ordinary garden borders, but like all bulbs, they will not continue to prosper unless properly nourished and grown till the new growth is perfected. The leaves are one-half inch wide and about eight inches long, flowers of good substance and fragrant.—Field and Farm.

FLOWER DISEASES.

In carnation bud rot, the petals rot before the buds open, or immediately after. In severe attacks the buds will never open, while in lighter attacks the flower will partially appear, but begins to rot before it is fully expanded. The only effective treatment is to pick off the affected buds as fast as they appear and destroy them. Spraying with Bordeaux mixture has been tried a number of times but has not proven effective.

Rose black spot may be overcome by spraying with Bordeaux mixture before the buds unfold. The solution used should be four pounds copper sulphate and six pounds of lime to fifty gallons of water. Ammonia copper carbonate should follow once each week. The diseased and fallen foliage should be gathered and burned.

FURNISHING THE PORCH.

The porches of a country house are now quite as important as the living rooms. They are built wider, in order to give plenty of space for furnishing. Rag carpet rugs make a serviceable covering there, as well as for the whole house. Sewing carpet rags should be a popular pastime this summer. Now that the rag carpet is so fashionable, even the best stores are dealing in it.

WINDOW GARDENING.

Geraniums will bloom earlier and better if put in small pots and besides they are much more convenient and really look better in windows.

The modern window sill is too shallow in depth to hold large pots. A very fine plant may be kept in bloom and good condition awhile in a very diminutive pot by using once a week liquid manure which is immediately appropriated by the roots. Soot, ground bone and ammonia are excellent also.

A simple shelf may be made for the window by slipping a board eight or ten inches wide under the lower sash and letting it rest upon the window ledge; cover with drapery to match the room furnishings, and allow it to fall over the front and ends a few inches; cover the top with a newspaper to catch any litter, and if small pots are used a display will be made. Turn the pots daily so as to avid the one-sidedness so common, and which spoils the appearance of many fine plants.

Dig around the plants occasionally, and probe in fissures which open into the saucers so as to admit air to roots and thus prevent clogging.

The Vegetable Garden

THIS MONTH.

THIS is the "betwixt and between" month but the vegetable garden may yet furnish opportunity for new planting.

Of course all earlier plantings must have careful watering and cultivation. Run out the weeds, run in the water. The cutworms are gone but there are others. Watch 'em.

Plant lettuce, radishes, corn, beans, and if you have'nt a plenty, put in melons and spinach. Pole the beans and tall peas.

Eat a little green corn to remind yourself how wise you were to make that extra early planting of fine sweet corn.

Spray the tomatoes with Bordeaux, and if the lice, aphis, are still bothering give a touch of whale oil soap, or if too busy to mix it and get down the pump, shake some fine ashes over them through a "mosquito bar" netting bag.

Don't work too hard, but just hard enough, and see if the garden does'nt taste better than the Chinaman's wilted truck.

SUMMER VEGETABLES.

It is rather late in the season for planting vegetables as it is now rather between seasons, too late for spring and too early for fall work. Still there are many classes of vegetables which can be sown for a succession of crops and in order to keep the table going. Beets may be planted at any time and, with proper care will grow rapidly and do well. Beans can be relied upon to give abundant string beans for the table and to ripen before cold weather sets in. Sweet corn may be sown with every assurance of plenty of roasting ears. Tomatoes may be set out for a late crop. Cabbage and the various members of this family, cauliflower broccoli, Brussels sprouts, etc., are always in season, and plants may be set out now for late crops and seed sown for plants for later setting. The summer season is not the best for growing good cabbages, as the hot weather forces them too rapidly and they are not so tender as when grown in the cooler season. Still, for a succession, they are always ready and with care will give good results. Potatoes may be planted for late fall use, and in fact most of the common summer varieties will yet do well if given proper care.

VEGETABLE GROWING.

With the soil and climate of California there is no reason why the owner of a small piece of land should not have fresh vegetables for his table every month in the year, and none taste so good as those which are gathered fresh from the garden and passed at once through the kitchen to the table There is no comparison between such and the stuff that has been hauled over half creation in the pedlar's wagon, or exposed to the hot sun for hours on the huxter's stall. Vegetables are so easily grown here that too many of us pass them over in utter contempt, as not worthy of our labor, and yet such labor, small as it would be, would be amply rewarded by the results. These requisites are demanded for growing good vegetables: Cultivation, irrigation, fertilization: The soil has got to be constantly stirred to keep down the weeds and let in the air, without which no form of vegetable life can thrive; all vegetables are shallow rooting, many of them not penetrating the soil over two or three inches, and unless there is ample moisture they will soon perish from drought. The soil must be kept damp by frequent applications of water, and these should be copious as well as frequent, the ground should be kept moist for at least a foot in depth and never allowed to dry out. Table vegetables are gross feeders and require abundant fertilization. Whenever a crop has been gathered, liberal application of well-rotted stable manure should be applied before a second crop is planted, and this second crop should not be the same form of vegetable as the first, but there should be a constant rotation of crops. With these hints followed, and proper care exercised in the selection of varieties suitable to the different seasons, there is no reason why anyone, with a few square yards of spare land, should not grow his own vegetables and always have them fresh and crisp for use.—J. I.

LIFE AND HABITS OF CUTWORMS.

There is so much being said about cutworms, often called army worms, that is in some ways misleading, that I will give my version.

I have made a practice every year when we are troubled with cutworms of breeding them out in large numbers for the purpose of getting good specimens for my insect case; to settle differences of opinion, and to ascertain what per cent. of the worms are parasitized.

Our cutworms are the larvae of a noctuid moth which may be seen in March or the early part of April flitting over the flowers in the twilight when we are to have what we term a cutworm season.

In a very short time after the cutworms begin to appear, and trouble follows. When we see the moth flying it is time to prepare for combat with the worms. The more weeds or alfalfa we have around us the more we are troubled with worms.

One orange grower told me that he thought he would not grow peas any more as a cover crop because the worms breed in the peas.

If the cover crop of whatever kind, peas, vetch or weeds are plowed under before April first, and all surrounding weeds disposed of at the same time I will venture the assertion that all worm troubles will be nominal. I have never yet seen cutworms trouble an orchard unless there were weeds or alfalfa for them to breed on.

When cutworms are in an orchard in numbers the effective way to avoid damage is to clean away under the trees and trim off the branches so that the cutworms cannot reach them from the ground and in that way get into the trees; then band the trees with either tree tanglefoot or with tanglefoot fly paper; we have tested this method and it works well.

We have been troubled with the pests this season and they were also much in evidence here two years ago. Heretofore they have appeared only once in four years.

A great deal has been said about the hot weather killing off the cutworms. If a few of the worms start out to travel and get caught in the hot sun-light and cannot get into the shade quickly the heat will kill them; but nature has given them understanding or intuition enough so that when it is going to be hot the worms get into the shade or into the earth, where they are safe until nightfall, their natural time for feeding, when they may be found in full force getting their meals.

They have their natural enemies however; one a large, black beetle called the Searcher, Calosoma scrutator; this enemy both in the larva and in the beetle stage eat cutworms voraciously. I have known this beetle to be confounded with the Pinacate-bug; not because it resembles the Calosoma, but simply because it is a black bug nearly the same size.

Our most effectual enemy of the cutworm is an ordinary sized fly much resembling the house fly and bears the name Frontina frenchii. And in breeding the worms out sometimes I have gotten all moths and sometimes all flies. These flies lay their eggs on the worms as they are travelling. and after the worms go into the pupae stage the egg of the fly hatches out a maggot which eats the pupa and then in its turn the maggot pupates and from this pupa emerges a fly.

It is from the effect of this fly that we may attribute our immunity from cutworms in what we term off years, as often from sixty to ninety per cent. of the worms are parasitized by these flies.—S. A. Fease.

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

California Horticulturally

A NEW ALMOND.

THE worst feature of the almond is its uncertainty as a bearer. If we could produce an almond that would give crops with any degree of certainty, there would be more money in it than in any other fruit. The almond is a very early bloomer, being the first of any of the fruit trees to come out in blossom. It is, therefore, subject to frost, to heavy rains which wash the pollen out of the blooms, it is subject to high winds and all the vicissitudes which come in the late winter months. Escaping these, it is more subject to Red spider than any other of our orchard trees, and altogether cannot be depended upon for crops and too often it is found unprofitable. What is wanted is a late blooming, spider-resistant almond and one possessed of the good qualities of those now grown. We note that C. F. Bantham, of Chico, claims to have produced a superior almond that seems to cover these requirements, and which he has named the "Bantham Everbearing." This nut seems to have been a chance seedling. The past two seasons have been very short on almonds, yet Mr. Bantham claims that his trees of this variety were loaded, yielding an average of thirty-nine pounds to the tree. It is sincerely to be hoped that this tree is all that is claimed for it.

PLANT LICE ON CABBAGES.

Now is the season when the whole of the aphis family is doing its greatest destruction and its members appear in great masses on all forms of tender vegetation. The vegetable gardener especially is suffering from their depredations, and the cabbage is perhaps the greatest victim of their destructive work. Fortunately this insect is one of the easiest handled. It is soft-bodied, very susceptible to changes of temperature, washed off by rains or devoured by lady-birds and other insects. Where they are doing damage to young plants, wood ashes dusted over the plants from a cheese cloth sack will destroy all that are touched; the kerosene emulsion is also one of the best remedies and a wash of whale oil soap, one pound to six gallons of water, applied hot will check them on any plants which they attack.

SERIOUS LABOR SHORTAGE.

The following statement is sent out from Porterville, Tulare county:

"Hundreds of tons of farm produce in this section are being burned by farmers in order to clear the ground as there is no available help to harvest the crops."

It seems impossible that this can be true, but it is true that there will be heavy losses due to the fact that sufficient help cannot be secured to save the crops this season. Conditions are even worse than last season, and with the great and increasing demand for labor in the cities, and the constant drain on the country, there is little hope for relief for the farmer this season at least. He will have to do all the work he can with the aid of his family, and trust to providence for the rest.

AN ENEMY TO BERMUDA GRASS.

Some one has discovered a grass which is so hardy that it will run out Bermuda grass when planted among it. We opine that the next thing which will be wanted will be something to kill this out, for anything that can run out Bermuda must be worse than Bermuda, and we have always been of the opinion that, except Johnson grass, this was the toughest thing to get rid of, when once established, in the whole vegetable kingdom. We shall watch the other fellow's experiment with much interest, but for ourself we shall let it alone.

APHIS ON HOUSE PLANTS.

Plant lice on house plants, or in the garden, on a small scale, can be handled with tobacco smoke, which is fatal to them. Get some tobacco stems, which can be secured from most seed stores or tobacco factories, and make a smudge of them in an air-tight room or receptacle. Another remedy is bi-sulphide of carbon, which can be had at any drug store. Put the plant in or under an air-tight box, an old can will do for small plants. Pour about two teaspoonfuls of the fluid into a saucer, cover the plant with the box or can, with the saucer and contents inside, bank a little soil aroung the bottom of the can to make it air-tight, as the gas is heavier than the air and will run out, if there is means for its escape, and leave it for half to three-quarters of an hour. Care must be taken in handling this stuff, as it is very inflammable and will explode if brought near a fire. So the operator will do well to lay his cigar aside while using it and not apply it by lamp light.

POTATO BLIGHT.

For several years past there has been much complaint of potato blight, and in some sections the disease has been so serious as to materially affect the output. Like very many of our blights, this disease is caused by a parasitic fungus, the spores of which are on the seed potatoes usually and ready to spread to the whole plant as soon as it begins to grow. Care should be taken, as far as possible, not to plant seed from an infected section. If there is any suspicion, the seed potatoes should be dipped in a solution of sulphate of copper, treated very much as seed wheat is treated for smut, or a solution of formaldehyde, a pint of formaldhyde in thirty gallons of water may be used. Soak the seed potatoes in this mixture for two hours. If there is any fear of blight, spray the young vines as soon as they appear with the Bordeaux mixture, and repeat later in the season.

A BOOM IN WHEAT.

In nearly all parts of the world where wheat is grown the crop this season is very short, and most of the exporting countries will have all they can do to supply the home demand. In Russia there is suffering and actual starvation in the wheat sections; in Argentina the crop is reported as very light, almost a failure, and like reports are received from all parts. In consequence there is already a boom in wheat prices, and those of our California farmers who have wheat for sale this year will do well. Unfortunately, we are in a like condition with other wheat growing sections.

"Are we alone?" asked one of the villains of the piece of his brother conspirator.

"No, guv'nor," came a voice from the gallery, "but you will be tomorrow night."—London Tatler.

With the Citrus Growers

CAPILLARITY.

WE HAVE been asked to explain the action which causes "tubes to form in the soil" called Capillary tubes which let the water out of the ground during evaporation.

There are no so-called "tubes" formed in the soil. The idea has become general perhaps through the explanation given of the action of water in the soil. It is best explained by the illustration afforded by the action of water in tubes. This action is due to the same force that makes things fall to the ground. The real force is gravitation, but in the case of the water in the tube (and the soil) it appears to be the opposite, but this is because of the difference in form and density of the different elements. The force which is exerted by gravity in this case is tension. For instance, when we blow a soap bubble and leave it on the bowl of the pipe and take the stem out of the mouth, leaving a free passage for the air from the inside of the bubble out through the stem of the pipe, the bubble will gradually grow smaller and finally form a straight diaphram over the mouth of the pipe and, at the same time, draw up a large drop of water that hangs at its lower end. Now if it were possible to have a marble or any substance inserted in the bubble without breaking the thin film of soapy water, it would squeeze the marble with a certain amount of force. If the substance were irregular, the bubble would become the same irregular shape. But it is not necessary to insert the marble. Touch it with a drop of the liquid and it will immediately travel around and cover the entire surface by the same force that draws the bubble back into the pipe. Touch the marble with another drop and it will travel around quickly to distribute itself over the surface and increase the thickness of the film. Repeat this often enough and when the amount of liquid becomes so large that the gravitation power of the earth more than equals that of the marble, a portion of the liquid will drop off. To illustrate how this acts, take two corks of equal size an weight and place them in a tub of water. They will be attracted to each other with equal force. Place a smaller cork near one of them and they commence to travel toward each other at once, the smaller one traveling the fastest that they bump together. In the case of the over-wet marble the earth pulls the extra water away from it. The amount of water is not properly proportioned. The water clings to the marble beacuse it is easily separated into small particles and each individual particle is attracted. Now if another marble is allowed to touch the over-wet one the fluid will at once travel over its surface till it is equally as wet provided the earth has the same pull at both. For this to be so, both ma bles must be on a level. If one is above the other the earth pulls hardest on the under one, consequently it is the wetest. Now place several marbles in a heap and wet the under ones and the moisture will travel from one to the other till they are all wet, but the lower ones will be the wetest. There will be a connecting point where the marbles touch at which place the film of water is the thickest. Now separate the marbles slightly and the film at that point will decrease in area and less water will travel from the lower ones to those above. Now instead of using marbles take coarse shot and the films of water at the points of contact will be broader than in the case of the marbles. the relative sizes being considered. Make the shot small enough and the films of water will increase in thickness at the points of contact till all the spaces are filled up to a height where the pull from the center of the earth equals the tension. Now a glass tube will show the appearance of this action plainly. Place one open at both ends, in a cup of water and it will run up the sides a short distance. Use a smaller tube and the water will rise a little higher. That is partly because there is not so much water to raise in the last case. This serves to illustrate the so-called tube action of the soil, but the spaces in the soil through which water travels from one particle to another are no more tubes than a promiscuous pile of lumber is a house.

The practical application of the action of water applied to the marbles and different sized shot and the glass tubes is this: If the soil is allowed to remain packed, which is a condition rendered when the particles are very close together, the moisture will travel form one to the other more quickly than when placed slightly apart. When it is desired to bring the moisture close to the surface, packing to bring the particles close together will accomplish the end. If it is desired to shut off and stop the passage of the moisture from one particle to another, separate them by cultivation.

The White Fly in California

The dreaded White Fly (Aleyrodes citri) so long a serious pest in Florida has invaded California, and so far as can be learned, has been here for the past two or three years.

So far as known it is yet confined to about 1000 trees in or near the city of Marysville, Yuba county. These trees are badly infested.

E. K. Carnes, Deputy Horticultural Commissioner, has made a thorough investigation and reports that without question the problem is before us of eradicating this greatest pest of the citrus industry.

It is to be hoped that most energetic action on the part of State and County authorities will wipe it out before it gains a stronger foothold.

While the present point of infestation is six hundred miles from the greater citrus producing sections of the State, the gravity of the situation demands instant action.

FEED THE TREES.

Experienced growers know that orange and lemon trees are gross feeders, and hence respond quickly to an application of plant food to the soil. In California, and for that matter in the arid regions quite generally, the soil is naturally rich, and when the tree is planted on virgin ground, it will do well without any application of fertilizer for the first few years; after that, however, some recognition must be given the orchard in this regard. Its extent and character is obviously a matter of local conditions, and act in compliance with the best practice of the successful and experienced grower in his locality. In sections where the soil is shallow it is expedient to apply a fertilizer every year from the time the orchard is planted. In the rich soils of California, it has been found that nearly all the subsidiary elements of plant food are present, and hence only the four leading elements must be supplied, viz., nitrogen, phosphoric acid and potash, and in rare cases lime. These must be replaced in the soil of orchards subject to constant cropping. The intelligent grower, therefore, will be quite apt to see to it that his trees do not suffer for the want of nitrogen, phosphoric acid and potash, because these are the elements which the crop annually draws from the ground, and which must be replaced.

The experience of orange growers indicates that the quality and quantity of the fruit may be very largely controlled by fertilization, and as oranges are purchased entirely upon their appearance and quality, this becomes a very important consideration throughout this region. Fertilization should be carried on with but one object viz., to enhance quality and quantity of fruit.

Touching kinds of fertilizers and values of stable manure, a report to the Riverside Horticultural Club on this subject contains the following suggestive paragraph:

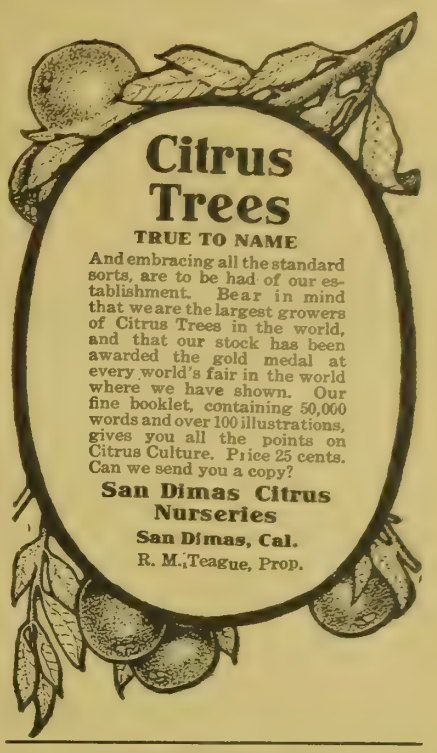
"The question of fertilizers for the orange orchard has in some form been almost continuously before the club. What kind of fertilizers are the best, and how and when they should be put on? are questions often asked, but never as yet answered to the satisfaction of all. It is known that the different commercial fertilizers on the market are good, and when freely applied they generally give satisfactory results. But growers believe that they are too expensive, and that by buying the chemicals and doing their own mixing, or by applying the chemicals in suitable quantity to the soil without mixing, they may reduce the expense about one-half. There is a growing conviction among orchardists that stable manure is one of the most valuable fertilizers, when it can be secured at reasonable figures. One small Navel orchard in Riverside, fifteen years old, a part of which has been fertilized exclusively with stable manure, has borne regularly, and the fruit has been fully up to the average standard of quality."—From Teague's Citrus Fruits.

"Tried your new auto yet?"

"Yep. Had a fine ride."

"Go fast?"

"Not so fast as the cop. That's where the fine came in."—Philadelphia Public Ledger.



Citrus Trees
TRUE TO NAME
And embracing all the standard sorts, are to be had of our establishment. Bear in mind that we are the largest growers of Citrus Trees in the world, and that our stock has been awarded the gold medal at every world's fair in the world where we have shown. Our fine booklet, containing 50,000 words and over 100 illustrations, gives you all the points on Citrus Culture. Price 25 cents. Can we send you a copy?

GENERAL AGRICULTURE.—Disk Harrowing Alfalfa, 601.
QUERIES AND REPLIES.—Lump-Jaw or Actinomycosis; Mange on Horses; Loquat Seed for Stock; Curl Leaf of Peach; Opening of San Jacinto Forest Reserve; Apricot Disease; Soft Scale; Diabrotica; Staking Malagas; Eucalyptus and Clover; Powdery Mildew on Apples; Legal Queries, 602-603.
HOUSEHOLD DEPARTMENT.—If We Knew; Tony's Search; Hints for the Cook; Dont's for Boys and Girls; Suggestive French Proverbs; Once Upon a Time; Mistakes in Maxims; Not the Historic Fort, 604-605.
THE PRODUCE MARKETS.—Los Angeles Market; San Francisco Market; New York Citrus Market; California Citrus Shipments, 604-605.

THE WHITE FLY.

The unwelcome news that California has been invaded by the Florida White fly is verified. It has appeared in one or more counties and is creating consternation among citrus growers.

The fact that so little is known about its character—except that it is a most dangerous and destructive enemy to citrus trees, as well as several other kinds of plants,—makes its eradication the more difficult. Its ravages are a bad as the scale and it must be handled promptly and severely to get rid of it. Fumigation is tne only remedy so far known. No parasite has been discovered that will check its ravages or destroy it.

If it were possible the State ought to cut down and burn every infested tree and plant, and pay the owners for the trees so destroyed. One thing is certain, California citrus growers are confronted by an enemy which must be exterminated at once or the groves in the State will perish in an incredibly short period.

THAT ROAD COMMISSION.

The Supervisors of Los Angeles county will have a good-roads commission to appoint within a short time. Upon the character of the members of this commission will rest the fate of the bonds asked from the people.

If the Supervisors appoint a commission composed of men who are politicians only, and know nothing about road making, the bonds will not be voted. They ought not to be voted. If on the contrary the selection of the commission is a wise one, if the members are practical, up-to-date road builders with characters well established for honesty, the people will, we believe, vote the bonds asked and Los Angeles county will enter upon the inauguration of a system of good roads which will make the county famous. We need good roads. They are of the first importance to the county, but the people must be assured that practical, honest men, not petty politicians are to handle the $3,000,000 asked, and that the County is to receive an equivalent, dollar for dollar, in the roads that are to be built.

The success of tne vote on the bonds to build the roads is up to the Supervisors. It depends entirely upon the complexion of the members appointed on the good-roads commission. If the commission is unsatisfactory to the people the bonds must be defeated.

THE PLODDING MAN WINS.

The secret of success, in whatever vocation, is tenacity. The man who undertakes a proposition and falters is lost. Conversely the man who sticks to whatever he elects to follow through adversity is the winner in the long run. Of no occupation is this truer than of agriculture. The farmer, fruit grower, poultry raiser and stock breeder are beset with drawbacks. A dozen unfriendly conditions surround him from the hour he embarks in business to the end of his career. He has troubles all the time, but he has corresponding pleasures in overcoming obstacles and winning success at last.

We have in mind, as an example, of this character, a young farmer near Glendale. A few years ago he bought the tract of land on which he now has a comfortable home, settled down to work it and built a home thereon and a competence. He struggled along amid adversity, bad conditions and worse health. At times he was discouraged but he never flinched. After several years of this sort of life the tide in his affairs took a turn for the better and today we are told by one of the prominent citizens of his town, that this man is worth $20,000. This fortune has been builded out of reverses, is substantial and but the beginning of wealth in the years to come. From this on his way will be easier and his profits larger from year to year.

It is the old story of work and wait. The man who works and waits is the man who wins provided he keeps pace with the age in which he lives. The instance cited is one of thousands of like kind. Rarely does an industrious, progressive farmer fail. It is the man who tires of work and reverses who never accomplishes anything; the man without glue in him to stick to one calling is the man to whom wealth never comes. To struggle with the "ups and downs" of business and overcome the "downs" is the right way and the way to succeed finally. In fact, it is the only way. If the Cultivator had any advice to offer the struggling young man in the field of agriculture to day, it would be to hold fast, improve with the times and never falter. The dark days are the days of experience and experience is the mother of all future results.

HOW SHALL WE TEACH AGRICULTURE?

The coming to California, in July, of several thousand school teachers ought to be the occasion for disseminating a great deal of practical educational thought. In this number will be men and women from every State in the Union, representing the varied conditions of climate and agriculture throughout the United States. Naturally among this number too, there will be representatives of great agricultural institutions, and these professors of scientific farming ought to be able, and will be able, to impart useful instruction as to the best methods of teaching agriculture in the common schools.

The old method the farmer adopted of giving to his son and daughter the information, he, himself, possessed regarding the farm, its live stock, its orchard, its field crops and its permanent improvements, was that of example. It was the simple process of allowing instruction to "filter through" the mind. This was the method used on the father, and of course, he was not to be blamed because he did not understand any other process of imparting practical, farm knowledge. The methods adopted in teaching agriculture to young people in this day are new in themselves. It has been but a few years since the National Committee on Scientific Agricultural Teaching made its first report, but since that date wonderful strides have been made all along the line, until at the present time, we are confronted by an entirely new process by which the theoretical is eradicated, and the practical is made to predomenate. The time has come when young men are seeking to know the answer to the question: "How shall we teach Agriculture?" We remember recently to have heard a learned professor from the State University make an observation like this:

"It is impractical to educate all the boys and girls of the country to be doctors, lawyers, preachers and teachers, as we have been doing in the years that are gone, because not one boy in a hundrd can hope for a successful professional career." This was a perfectly honest statement, as borne out by statistics; the fact is, that less than five per cent. of the boys in the common schools ever reach the high school; only about one per cent. reach college, and less than that, the University. The importance of the question then, "How Shall We Teach Agriculture?" is one of the most live and interesting of the educational questions before the country. While considering what to teach, the materials, views and information the school teacher possesses, are of great importance.

Teachers Fitly Qualified.

There is no class of persons more fitly qualified, if they possess the proper information to promulgate agricultural instruction than the teachers in our common schools. More than fifty per cent of these, we may safely estimate, have been reared on the farm, or on the ranch. They have absorbed many farm views and naturally their powers of observation are trained along agricultural lines. Such teachers, themselves, require but the physical implements to teach agriculture in its most scientific and understanable form; practical experience is a teacher which in all ages has accomplished the practical results in life. Scientific facts, when clearly and simply stated, and supplemented by practical explanations, are readily understood by children of even tender age. The children then become educators of the parents; they carry with them suggestions which, made to the fathers and mothers, result in unbounded good to the life of the farm. The country school is the vehicle for inculcating scientific principles in farming. The teachers should be supplied with tools by which to make practical demonstration, to the end that scientific knowledge may take useful form and be of lasting benefit. Those teachers who only use the text book are theorists and their instruction practically avails nothing. There are special works which might be adopted in the country schools; towit, the school garden, in which the culture of plants and flowers naturally leads up to instruction as to the methods eradicating the pests which infest those plants and flowers. The window garden for the country school is a modified feature of this system; agricultural research is a feature which might profitably be combined with school composition work and in itself presents a valuable course of topical reading. The supply of reference books needed for starting an Agricultural library is so inexpensive as to debar no school from obtaining it. Walks afield with classes in spring time, or in harvest, are most instructive; visits to stock farms, hot houses, dairies, orchards, poultry yards and nurseries are most useful and afford pleasure with recreation.

Basis of Higher Education,

When our Boards of Education undertake this practical work, in some of its several forms, our common schools will become as they should be, the basis of our higher education. The child and the teacher will get a deeper insight into things that make up the human life, than has heretofore been obtained in the common life. The child will recognize that "going to school" is indeed the preparation for a useful existance. Farming will present itself as a thing of system and reason, and enlist the active interest of every child who is an attendant thereat. We believe that every common school, and every normal school in the country, should embrace a curriculum of the best methods of teaching agriculture, as well as of supplying them with material to demonstrate fundamental principles. State legislatures should provide the necessary equipment for the normal schools to render their efforts in elementary agricultural instructions effective and thorough. Our Boards of Education throughout the land should wake up to the importance of putting into operation every teaching fact now developed, or being developed, in the agricultural field, to the end that we may produce a class of citizens out of our common schools, and our normal schools, thorough in every department of the field of agricultural education. It is up to such great teachers as David Starr Jordan, Benjamin Ide Wheeler, and Edward J. Wickson, all of California, to "lead out" along this line and show our eastern educators the value of such instruction as that of which we write.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

McKim Bros. at Imperial will ship 22 carloads of hogs to market this year.

State Dairy Inspector Starr predicts a great dairy future for Imperial Valley.

The annual round up of cattle from all parts of Antelope Valley will take place next week.

Grain crops in the Antelope Valley are reported by the Gazette to be in exceedingly fine condition.

Celery Growers' Association of Southern California changed its by-laws at its meeting on June 3rd.

Salton Sea is now 205 feet at its surface below sea level, while at its bottom is known to be 287 feet below sea level.

The warm weather of the desert is reducing the Salton Sea; one paper states a reduction of one foot in three weeks.

The Standard says: "The new hog crop is beginning to ripen and will be harvested within the next two or three weeks."

W. W. Howard, the white leghorn man, has purchased real estate at San Jacinto for the extension of his poultry yards.

Lancaster is becoming quite a poultry shipping point. Several new ranches have been started within the past two months.

Palm Avenue school at Rivesride is "getting back to the soil" and the youngsters attending there are having a thorough drill in garden work.

Grain in the Imperial Valley is reported not so heavy as anticipated earlier, but a very fine crop. Barley will be about one-third of last year's yield.

A Santa Barbara experimenter claims to be able to evaporate eggs which will be later put upon the market, more particularly for use in the army.

Friends of the new county of San Antonio are working hard to make a new county out of the eastern Los Angeles and western San Bernardino counties.

A large cabbage shipper, Thomas Strain of Fullerton, is being sued to compel the completion of contract. The claim is made that he purchased stock of the grower which he maintains he was simply handling on commission.

The Colorado river continues to rise and great fear is expressed that the levee may not hold. The Southern Pacific has a patrol at danger points and every effort will be made to save the work which was put in at such vast expense last year.

The stockmen of San Diego county are requested to meet at Steiner Hall, in Escondido, on Thursday, June 20, 1907, for the purpose of effecting a permanent organization of the stockmen of the county, and to take steps to eradicate the Texas fever or tick disease.—Escondido Times.

The work of getting the Yucaipe Valley ready for settlers is progressing rapidly. Surveyors are at work subdividing the huge tract into small farms and platting the same. Alfalfa is to be sowed over a large area, and trees set out on several tracts. The land is to be put under irrigation whenever needed by means of wells and pumps.

HORTICULTURE.

Pomona reports a setting of a big crop of oranges.

Work at the canning of blackberries is now on at Pomona cannery.

Berrydale, Los Angeles county, is shipping 40 to 50 crates of strawberries daily.

Logan berries are ripe at Hemet; the quality is fine and the crop a large one.

Navels from Arlington Heights are all shipped; other varieties will soon be off the trees.

S. M. Bixby, of Imperial, has sold $30 worth of dewberries from one-twenty-fifth of an acre.

A patent orange-wrapping machine has been installed at the Spruance packing-house San Gabriel.

Redlands has shipped its last navels. The aggregate for the season is about 3150 cars for the season.

Santa Ana packing-houses are still handling a few oranges but the season's output is practically all in.

Apricots are almost ready to pick at Hemet, the season commencing about a month earlier than last year.

The cantaloupe, cucumber and squash shippers at Brawley are up to their ears in fruit shipping these days.

From Imperial there will be shipped about 12 carloads of early table grapes which will aggregate about 180 tons.

Manager Brown of the San Joaquin Ranch near Santa Ana has just finished the planting of 60 acres of oranges.

The San Fernando Press reports the stealing of oranges conducted in that section to be almost unbearable by the orchardists.

One vineyardist in Imperial Valley has sold his grape crop for this year for $125 per acre, and this only a two-year-old vineyard.

Highgrove is quite puffed up over the fact that some of her Cerrito brand of navels sold last week in New York for $4.65 per box.

The Imperial Standard says that the returns from the grape crop within a radius of four miles of Imperial will aggregate $500,000.

A convention of forest rangers of Southern California was held at San Bernardino recently; about 40 rangers were in attendance.

The San Joaquin Fruit Co., at Santa Ana, is improving its ranch property by the extension of pipe lines for more economical irrigation.

The Submarine of the Coachella valley maintains that the date experimental planting at the government station has already proved date growing to be a success.

Thermal will ship about the same number of cantaloupes as she did last year, the acreage is smaller but a better crop obtains; about 75 carloads will be the output.

The warm weather has decreased the pest of cutworms in most sections of Southern California and ended the fear that possibly the whole orange crop might be wiped out.

Redlands papers complain of shipments of purple scale on fruit which was received at the marmalade factory; shipments from all infested sections have been prohibited.

Northern California

AGRICULTURE.

Fresno county has had its visitation of grasshoppers.

Brownsville, Yuba county is to have a new creamery.

An experimental planting of tobacco is being made at Florin.

The Burdell creamery near Point Reyes was destroyed by fire recently.

Wheatland hay and grain growers have finished their harvesting of a fine crop.

A large woolen mill has been established at Marysville and is being run to its limit.

Pajaro appeals for farm help to assist in the gathering of the crops of the Pajaro Valley.

Prof. Fowler of Berkeley will conduct a Farmers' Institute at Alpaugh on June 21 and 22.

The Tulare Grange held a special meeting recently which was addressed by State Master Griffith.

Wheatland reports a very heavy crop of hops with scarcely a vine in the field not flourishing.

Preparations are being made for a fair of Placer county products to be held in Rocklin in September.

The wool and "scouring" plant at Marysville is making Marysville a great woolen shipping center.

Secretary Filcher of the State fair is making strenuous efforts for a "for sure" Agricultural fair this year.

Marysville is experimenting in the planting of tobacco, and to this writing the experiment promises well.

The State Forester is investigating a grain fire near Orangeville which was started by picnickers. Arrests may follow.

A new irrigation canal supplying Glenn and Colusa counties is 50 miles long of 60-foot ditch and 24 miles of 30-foot ditch.

A farmer near Orangeville demanded and received $56.25 for damage to his crops caused by picnickers setting his field on fire.

The Roberts ditch near Colusa is again carrying water for irrigation which is increasing the value of real estate under the ditch.

One of the improvements in Sequoia Park, East of Fresno county, is the completion of a fine road-way in the "Giant Forest" road.

A new creamery is being built at Meridian, Sutter county, Cal., by Messers. D. L. W. Hoffman, M. A. Girdner and W. T. Mitchell.

The trustees of reclamation dis- No. 70 in Sutter county are putting in additional dredgers for new levees, and are repairing the old ones.

The Central Irrigation Co. having lands in Colusa county are advertising in the Eastern newspapers for settlers for their newly opened lands.

A scheme is on foot by which quantities of water will be pumped from Tulare lake to reclaim the barren plains along the western slope of the valley.

A cool and invigorating sea breeze is given credit for the saving of the grain and hay crops in Yolo county. It was feared earlier that the drought would cause a great shrinkage in the yield which is now found will be much better than anticipated.

HORTICULTURE.

Tehama reports good crops of almonds.

Newcastle reports a good season in cherries.

Most of the breaks in the leeves of rivers have been repaired.

Olives promise to be the heaviest crop ever in the Maywood colony.

Tehama claims she will produce 300 tons of dried prunes this season.

Reports as to peach blight are that the attack is much lighter than last year.

A bank has begun suit to foreclose the mortgage of the Geyserville cannery.

The highest estimate for the California prune crop this year is 65,000,000 pounds.

The Lindsay Gazette chronicles the planting of many Valencia oranges this season.

Santa Clara Valley prune growers are being offered four cents per pound for all sizes.

San Joaquin peach growers are being offered ten cents per pound for cured peaches.

Hearldsburg has an association of "boosters" whose aim is to encourage clean roadways.

Strawberry growers of Watsonville have made a fine clean up of this year's output.

Cherries which have been sold in the East brought excellent returns to the growers this year.

One hundred dollars per ton is being offered for the coming crop of raisins. This is the highest price for many years.

A 15 acre orange orchard near Porterville sold recently for $24,000. This is the top notch for orange orchards in that section.

The Porterville Enterprise says this will be as fine a year for fruit growers of Tulare county as they have ever experienced.

The prune pitting machine which has been invented at Santa Clara will take the pit from the pulp with very little if any waste.

The first carload of California deciduous fruits to go by freight this season left Vacaville Thursday, May 23, six days later than last year.

The pumps at districts No. 556 and 407 near Isleton have run the water from the overflow, so that now it is anticipated late crops will be given on those lands.

The first carload of deciduous fruits out of Vacaville this year contained 1,585 boxes of cherries, 255 cars of apricots, and one box of peaches, the first of the season.

Cora E. Erkert near Cloverdale has begun suit against a number of farmers for damage caused by constructing a dam, which cut her off from the water of the Russian river.

The farmers in Salinas Valley are taking steps to secure Federal aid in irrigating their lands. A mass meeting is to be called for sometime during the present month.

The farmers near Biggs are paying nearly twice as much as last year for help, and find that even at that some of their crops will be wasted for want of sufficient help.

Buy the World's Famous Egg Food No. 4

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis World's Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 5th, 1904—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.

"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Profit in the Poultry Yard

WHITE FACED BLACK SPANISH.

THE White Faced Black Spanish represent one of the oldest breeds of the Mediterranean class, and it is to be regretted that such an old breed with so good qualities has so little known history. In looking over some of the best works published on poultry we find very little devoted to the Spanish. Their real origin seems to be somewhat a doubt, some claiming that they can be traced back more than 100 years. The writer has from Mrs. W. H. O'Connor, who breeds

First Prize White Faced Black Spanish Pullet, Los Angeles, 1907
Exhibited by Mrs. W. H. O'Connor, Dolgeville

them, that her parents bred them when she was a child and that she has always been actively engaged since she was old enough to take any interest in poultry. That they were bred about the same then as now.

History.

Mr. Lewis Wright, who remembers the old Black Spanish, says that they were bred in England to a somewhat rough or "cauliflower" type of face, but that a second introduction of birds with smaller and smoother faces came from Holland, precisely that district of Europe which had been most overrun by the Spanish armies under the Duke of Alva. We believe that we are safe in saying that the Spanish were originally from Spain, and that they and the Minorca at one time were closely related.

The Spanish as now bred with thin, large, white face show quite a contrast from the Minorca. Aside from face, however, there are many points that resemble. They are of the non-sitting class and lay an extra large, white-shelled egg. In one respect they differ from many of our fowls, in that they lay either winter or summer in this climate of the Pacific Coast.

Standard Description.

Male.—The face "long, deep, smooth, free from wrinkles, rising well over the eyes in an arched form, reaching toward back of head and to base of beak, covering the cheeks and joining the wattle and ear lobes; the greater the extent of surface the better."

Comb should be single, of medium size, straight and upright, firm and even on the head, deeply and evenly serrated, having five points.

Back, of medium length and width; body, rather long; wings, large and well folded; tail, large, expanded, and main tail feathers carried at an angle of 45 degrees. Weight: Cocks 8 lbs, cockerels 6½ lbs.

Description of female: face similar to that of male but smaller. Comb: Single, large, drooping to one side, evenly serrated, having five points. Back, of medium length. Body, of medium width, rather long. Tail, carried at an angle of forty-five degrees. Weight of hens, 6½ pounds, pullets 5½ pounds.

Colors of male and female, plumage black, free from purple bars; shanks and toes, blue or leaden blue.

AROUND THE YARDS.

Mrs. S. D. A., Arlington, writes regarding fleas that are bothering her flocks. They attack both old and young—fastening themselves to their heads—and asking some remedy.

This flea at one time caused a great deal of trouble to poultry raisers in California, but until last fall or late summer had not been troublesome for some time. It then made its appearance in many flocks and caused considerable trouble, and no end of worry.

For relief to birds afflicted a good application is carbolic salve, or lard and sulphur. But you will be annoyed until you rid your hens of them. This can be done by spraying the houses with an immersion of distillate and crude carbolic acid. Or a solution of commercial sulphuric acid about six tablespoonfuls to one gallon of water. Sprinkled well in houses and yards about twice or

First Prize White Faced Black Spanish Cockerel
Exhibited by Mrs. W. H. O'Connor, Dolgeville

three times a week, for two or three weeks. Care must be taken to keep it from the clothes and hands.

To Good to Them.

Will you give a good remedy for diseased liver in poultry. Some of my largest turkeys have been dying and, on examination, found yellow blotches on the liver.—A Subscriber.

The trouble with your turkeys is you have been overfeeding them and not giving them enough exercise. If you keep too much rich food before them they will eat more than is required for health and growth, and they refuse to exercise, thus causing liver complaint. Keep them at work, and in case you have trouble give a liver pill and don't feed so heavy.

Turkey Facts.

Always feed on clean surfaces.

Turkeys cannot stand dampness.

Filth is especially dangerous to all young stock.

Save the earliest and best of young stock for breeders.

The plumpest bodies are found in the short-legged fowls.

It is advisable to breed from choice old hens as long as they live.

As a rule, medium-weight turkeys sell best—especially around the holidays.

Lice cause fully nine-tenths of the mortality among the young.

Yearling breeding stock, as a rule, do not produce strong stock.

While the young turkey is tender, the old ones are very hardy, and do not need any artificial warmth in winter.

Turkeys thrive better in an open shed with a high roost than they do in a closed house.

We recently had the pleasure of a visit to the yards of a lady breeder who had a system in poultry breeding the same as she did with her housework. One thing we liked was the plan of purifying the soil in her pens. She had two or three extra pens and in these spaded up the ground and sowed wheat. When the wheat was about four or five inches high she turned the fowls on it and sowed another yard, in this way she always had nice clean runs, to say nothing of the saving in green food.

Age has no effect whatever on the laying or paying quality of geese. The rule is that geese increase in prolificacy with years. They lay as many eggs twenty years old as they did when only two or three years old and the fertility of same is better. Of course, a proper keeping and feeding must have been practiced at all times. Fat geese are non-producers. A solid bran ration is detrimental to good results. A grass-run and liberty and a little oats at night during the winter season is best.

At this time of year many are tempted to sell their early hatched birds, because the prices are attractive. Our advice is not to sell the early hatched pullets as they will pay for themselves this fall and winter with eggs, besides, they will make better breeders.

If you have not already provided shade for your fowls and chicks, do so at once, as they must have protection from the sun. In many sections it is also necessary to have a windbreak, as the steady wind keeps them in an unsettled and restless condition.

If you have room near a stream or pond get some ducks. Get good stock or eggs from some reliable breeder and lay foundation for the coming season. There is money in ducks, and they are not subject to many of the diseases of poultry.

The danger of overfeeding is reduced to a minimum when all grain is thrown in litter of some sort. The fowls will be eager to scratch for it and in doing so they obtain the exercise that keeps them in a healthy, natural condition.

The best health promoter we know of is simply burned corn. Put the corn in a baking pan and put into a hot oven. Leave it there, stirring it frequently, until the grains are burned to a crisp black. The hens fight for it after having it fed to them a few times.

Some of our readers have addressed their letters to us without street number. We received them after a time, but all mail pertaining to poultry matters should be addressed care of the Cultivator Publishing Co., 115 North Broadway, Los Angeles. This will reach us without delay, and you will receive the desired information much sooner. Several inquiries were not received in time to answer last week.

"Don't you think that doctor comes oftener than he needs to?"

"How should I know what his needs are?"—Life.

PARTRIDGE WYANDOTTES.

The Cultivator believes in the good points of the various breeds of poultry being set forth by fanciers who have a love for the breed under discussion. And heretofore several articles have appeared. Below, Mr. L. E. Berkey gives his opinion of the Partridge Wyandotte. He is a warm friend of the beautiful bird and his article is well worth careful reading. Friends of other breeds are invited to set forth the good points in utility and beauty which their breed possesses.—Editor.

Too much cannot be said in favor of the Wyandottes' shape and beauty as well as their great utility points. I heartily endorse the good words that have appeared in your columns about the other varieties, yet I am glad to have this opportunity to mention a less known, but the most beautiful variety of all—the Partridges. I am sure it must be because the breed is deservedly popular that we see more illustrations of Wyandottes in our poultry press than any two or three other breeds.

Among the many varieties of this grand breed (no race suicide here—for it is the biggest family in poultrydom, and every one of these varieties have enthusiastic supporters,) none attract more attention at our shows than the Partridges. Their beauty never fails to attract. In the East they have become quite numerous, ranking next in numbers to the White and Buff varieties, but Partridges are less known on this Coast.

Description.

It is difficult to describe the Partridge accurately and yet briefly. To those who are acquainted with the Partridge Cochins, it is a simple matter, for we have in this variety simply a combination of Wyandotte size, shape, etc., with Partridge Cochin color.

To begin with, the male and female are not alike in color. The male should have a glossy black breast, thighs, fluff and tail, with red back, red hackle and saddle feathers striped or pencilled, with greenish black, dark gray under color and should be free from white in either surface or under color. The female should have a mahogany brown ground color with a very dark brown or brown black pencilling running around the feather conforming with shape of feather, except the hackle, which is similar to the male, and the tail should be dead black. The wing feathers are also black, but edged with brown; the pencilling on her body should be sharp and well-defined all over except the parts mentioned.

Originators.

The honor of originating this beautiful variety belongs to Ezra Cornell and a Mr. Brackenbury, of Ithica, New York, who co-operated in bringing out the Silver Pencilled Wyandotte also. About the same time Ed. Theim of Dennison, Iowa, also produced what has since been known as the western strain.

Cornell and Brackenbury used a Golden Wyandotte male with the Partridge Cochin female for their first cross. The next season they introduced Golden Pencilled Hamburg blood and the following season more Partridge Cochin blood. The western strain, I believe, claims a straight cross of the Golden Wyandotte and the Partridge Cochin. Mr. Robert Condee, of Los Angeles, also succeeded with this same cross and

Until the Chicks are over half grown, feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seed, meat, etc., in just the right proportion to make a full rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keep it, and will not get it, send $3.35 for 100 pounds, freight prepaid by us to any point in California.

MY EXHIBIT OF
WHITE, BUFF AND PARTRIDGE **Wyandottes**
Won 26 Ribbons and Special Prizes at the Poultry Breeders' Show, 1907
R. D. Box D87 L. E. BERKEY, Fullerton, Cal.

The big canal of the Central Irrigation Co. was opened last week, taking its water from the Sacramento river. It carries sufficient water to irrigate 250,000 acres of farming lands in Glenn and Colusa counties.

some very choice specimens of his strain (the Pacific) may be seen in Mr. Andrew's yards at Hollywood. One difficulty with this strain has been too light hackle and ground color in the females, but Mr. Andrews is patiently overcoming that fault.

Not So Hard.

One objection urged against the Partridges is that "they are so hard to breed. Beginning only two years ago with absolutely no knowledge of poultry, much less of the intricacies of breeding, I have produced several specimens pronounced by Judge Ellison last winter as the best ever found in the show room East or West, which does not look as if they are so "awfully" hard to breed. I attribute my success not to wonderful ability but to having the right foundation stock.

Frequently you hear people say: "Anyone can breed a solid-colored bird," but can they? I don't know a harder proposition than to breed an absolutely white or buff bird. I am breeding both of those varieties, too and have a good bunch of prize winners among them, good foundation stock and all that, but for results I am not prepared to admit that the Partridges are one bit harder to breed. The secret of it all is to have your males and females properly mated. The veriest novice may have the right foundation stock and correct mating and achieve success in a season where an expert dealing with less perfect foundation stock will take several years of pains taking effort and careful selection to secure the same results.

A Good Foundation.

Being a novice myself I feel it right to say to a beginner with this breed: "Get the right foundation regardless of expense." However, the costliest birds may not be the best. They should be bred in line. A novice cannot afford to experiment or blunder, at least most novices cannot. Do not get a male from one line and a female from another line and expect a perfect issue. You might accidentally get it. The chances are a hundred to one against it. Let a reliable breeder mate a trio or pen for you. Then stick to them, breeding in line and study your birds for several seasons. Perhaps later you can afford to experiment with "out-breeding."

Utility as Well as Beauty.

Pardon the lecture. Let me say in conclusion: The Partridge variety possesses all the good utility features of the other varieties. They are usually very docile and easily managed. They have a color not easily soiled and do not require washing for the show room. If anything, they are a little more round and plump and offer a little more breast meat than other varieties, when they come to the table,—and many a lady has remarked on the beauty of the plumage for millinery—therefore I watch my fowls closely.—L. E. Berkey, Fullerton, Cal.

NEW TOPOGRAPHIC MAPS.

The United States Geological Survey has recently published atlas sheets of the following areas in this State: Davisville, Dunnigan, Indian Valley. The price of these maps is five cents each. Purchased in lots of 100, they sell for $3. Applications for copies should be addressed to the Director, U. S. Geological Survey, Washington, D. C.

BLACK CLOTHING AND BEES.

That the old idea that bees are irritated by black clothing is something more than theory, has long been known to me, although a new demonstration of proof occasionally comes with interest. In the honey season, especialy during extracting, when the bees are inclined to feel irritated anyway, the black overalls and shirts so many young men like to wear are found to be especially objectionable to the bees—so much so that we nearly always warn a new helper not to bring them. In fact, the new man generally gets his instructions as to the kind of working clothes to bring—blue overalls (white would be better if they did not soil so quickly), lightweight, light-colored print shirts, and plenty of changes of both.

But with reference to black clothing.

"Only a short time ago it was my privilege to spend part of the day in an out-apiary belonging to one of Ontario's well-known bee-keepers. During the time I was there, although I walked all through the yard quite a number of times, hardly a bee offered to sting, and I concluded they were a pretty quite lot of bees. During the day the owner came to the apairy and together we started to go among the bees, when, presto! what a change. In an instant the bees were fairly swarming about the head of our bee-keeper friend, and it was more than funny (to the writer) to see the way he sprinted for cover to the honey-house. As I had been wearing a straw hat, and the bee-keeper was dressed in dark clothing and a black felt hat, it struck me as a clear case of the bees being aggravated by the dark garb, especially the black hat. At least, that was the only construction I could place on the matter by the victim—he "guessed they knew him, and were trying to even up some old score."—American Bee Journal.

WATER CHARGE RUMORS FALSE.

The farmers in the West have been greatly alarmed in the last few weeks by the persistent circulation of a report to the effect that the administration was preparing to make a charge for water derived from the National forests and used for irrigation and other general purposes. The report, it appears, has not the slightest basis of fact, and has been denied by officials of the Forest Service.

People of the sections of the West where irrigation has been such an important factor in development were naturally much concerned in the rumored charge for water coming from the National forests. The interests of people concerned with forestry and irrigation are much the same, as the steady flow of most of the irrigating streams is absolutely dependent on the preservation of the forest watersheds.

In a letter to Hon. Edward T. Taylor, of Glenwood Springs, Colorado, concerning the rumored charge for water for irrigation, Forester Pinchot says that he does not believe that there ever should be, or ever will be, a charge for water for irrigation. The erroneous report was founded on misrepresentations regarding the charges which electric power companies are required to pay for use and occupancy of lands in the National forests for reservoir sites, conduit rights-of-way and power stations. This charge is solely for the use of the lands, based on their value for such purposes, and is not in any sense a charge of water. The appropriation and use of water is regulated solely by the State and the Forest Service has no jurisdiction in the matter.

In the case of irrigation projects the Forest Service does not even charge for the use of lands for reservoirs and canals. Hundreds of permits have been issued by the Forester to occupy and use National forest lands for irrigation reservoirs and conduits, and such permits are always granted free.

ABOUT FARM POWER.

The simple gasoline engines manufactured by the International Harvester Company are doing much in revolutionizing farm work. Many is the place they are now employed where formerly slow, laborious hand labor had to be resorted to. There is hardly any limit to the times and places where power of some kind can be used on the farm. With the perfecting of gasoline engines a long step was taken toward lightening of farm burdens. With the perfecting of the I. H. C. engines, the farm power problem was completely solved. These engines were made not only reliable but also simple, so that farmers who are not supposed to be machinists could run them. The I. H. C. engines quickly made the tread mills and the old-fashined horse-powers a thing of the past. I. H. C. engines furnish an economical power because they use little fuel. They can be adapted to use alcohol as well as gasoline, and therefore are destined to be run cheaply. They can be had in many sizes, such as can easily be moved from place to place, and are especially adapted to light work.

Local International agents can supply catalogues and give particulars about these engines. If you need power or want to post up on power questions, call and take up the questions with them.

BLOW UP THE ANTS.

Ants are unusually troublesome this season. They can be gotten rid of by the following method. Pour a small quantity of bisulphide of carbon into their nest, cover for ten minutes with a wet gunny sack, then explode by dropping a piece of lighted newspaper over it.

The agent for the Department of Agriculture has been visiting the beet lands of Salinas to learn as to whether the fields there are infested with nematodes, a pest which has been a serious menace to the beet fields of Europe. He reports the Salinas fields to be entirely free from them.

Red Bluff reports the sale of a 1200-acre farm, of which 700 were in bearing orchards, principally deciduous fruits and almonds. The purchaser was a syndicate of Canada, and the purchase was made for the purpose of colonization.

The apple orchardists of Pajaro Valley are arranging for a horticultural fair to be held the last week in September. O. D. Stoesser, J. W. Sill and A. N. Judd are the committee on arrangements.

Peach growers about Fresno are being offered 8 cents per pound for peaches and are not manifesting any particular anxiety to accept even that. Ten cents would look better to them.

D. G. Alkin is improving the property of the Stone Brothers near Imperial which has the largest vineyard in the valley. There are now 375 acres of vineyard on the ranch.

General Agriculture

DISK-HARROWING ALFALFA.

FROM a bulletin of the University of Arizona Experiment Station by R. H. Forbes we quote the following valuable hints on disk-harrowing of alfalfa:

The disking of alfalfa is quite generally practiced wherever the crop is grown in this country. There are several good reasons for this procedure, varying somewhat in the order of their merit according to local conditions.

In the first place the sharp disks set at a slight angle split and spread the crowns of many of the plants causing them to stool and send up an increaseed number of stems. Little or no damage results from the operation which should be carried on in winter or after a cutting when the alfalfa is in stubble.

In some localities, also, the resulting mulch of loose earth is stated to conserve soil moisture at times when rainfall is slight or irrigating water scarce. To this should be added the observation that disking incorporates with the surface soil much fertilizing material, especially alfalfa leaves which are lost during the operations of haying.

Destroys Insects.

In some sections of the country disking operates against certain insect enemies of alfalfa by destroying their egg deposits and larvae. In Kansas and Nebraska grasshoppers are said to be reduced by early spring disking, and in Arizona it is not unlikely that hibernating caterpillers of the alfalfa butterfly, Colias eurytheme, are to some extent destroyed by winter disking alfalfa fields.

The soil itself is subject to certain untoward conditions to which disking and harrowing may be applied with advantage. As elsewhere the passage of hay making machinery and work animals tends to pack the surface soil thereby lessening the penetration of air and water to the roots of the crop; and in addition during our mild winter season alfalfa fields are usually heavily pastured by cattle and horses, sometimes for several months of the year.

Silt Blankets.

More peculiar, however, to Southwestern irrigation conditions are the silt-blankets resulting from the use of the muddy irrigating waters charateristic of the region. These silt-laden waters when applied to an irrigated field drop their load of detritus upon the surface of the soil in a layer decreasing in thickness from the head to the foot of the field. Inasmuch as alfalfa is a perennial crop which cannot be deeply cultivated these sediments accumulate from year to year in deposits which frequently attain a thickness of 3 to 4 inches. Since the sediments composing these deposits are usually of a more or less plastic character these blankets are often noticeably impervious to water and to air, limiting the supply of these essentials to the deep-root systems of the plants. The result is a decreased yield, especially at the heads of the fields where accumulations are thickest.

Cultivation by the means of disk and spring-tooth harrows, is the best available means of handling these accumulations in alfalfa. This treatment breaks up the blanket and allows better penetration of water and air into the soil. Also to some extent it incorporates these sediments with the soil, thereby making their fertilizing values available to the crop which consequently realizes benefit instead of detriment from them.

Ten Acres a Day.

One man with an eight-foot disk and four horses will get over about ten acres of alfalfa in a day. This work may be done in winter when teams are more at leisure; but it is probable that in summer also after cutting and before irrigating, an occasional disking to break up the sediment-blanket may be well worth while, especially on the upper ends of alfalfa fields.

Summary.

At a trifling cost, therefore, varying according to individual circumstances, the disk-harrow splits and spreads the crowns of alfalfa plants causing them to develop additional tops; it destroys the eggs deposits and larvae of certain injurious insects; it breaks up the silt-blanket resulting from the use of muddy irrigating water allowing better penetration of water and air to the roots of the crop; and to some extent it incorporates beneficial sediments and fallen alfalfa leaves with the soil.

It is quite probably, speaking conservatively, that for some or all of these reasons the average alfalfa crop in Arizona may be increased ten per cent. by disking. But the cost of handling the increased crop is not greater in proportion; therefore, the net profit of disking on the basis of the above estimate may be somewhat more.

Buy A Combination Farm

THERE is one place where you can buy grazing land for your live stock and irrigated land for farming purposes side by side—That is in Sunny Southern Alberta, Canada.

Just stop and consider the advantages of such an arrangement as that—For farming purposes you have a never failing water supply which insures your crop when you place seed in the soil—You also are assured of having a constant supply of water for your live stock.

On the irrigated portion of your farm you can raise most any kind of grain or root crops—you can raise forage for your live stock.

On the non-irrigated section you will have the finest range for your live stock to be found in the world. The native grasses on the plains of Alberta are rich in the fattening properties so much so that Alberta beef shipped direct from the ranges has come to be considered as fine as the corn fed beef of the States.

Good markets are one of the features of Alberta—the farmer has no difficulty in selling everything he raises at prices as satisfactory, considering the cost of production, as are to be had anywhere.

Combination farms in the irrigated district of Southern Alberta are to be had at a price so low and on terms so easy that everyone should own a farm. Of course, the irrigated lands cost a little more than the non-irrigated and that is the advantage of being able to get a combination farm. A live stock range can be secured very cheaply, while in other districts where nothing grows on non-irrigated lands the settler must pay high prices for every acre whether he desires to utilize it for live stock raising or not.

The water supply in Canada is unfailing because the government does not authorize the construction of more ditches than there is water to fill, and the heavy water supply comes down from the mountains just at the season of the year when it is most needed, during spring and summer.

Come to Alberta and get a combination farm—we will be glad to tell you about the low prices and easy terms—We will also be glad to tell you how to see the country at very low cost—It is a fine trip. Write us for information and then come up.

LUMP JAW OR ACTINOMYCOSIS.

What is "lump-jaw?" My cow has a bunch the size of a man's fist on one side of her jaw. It is hard, but not sore, apparently. Cow seems in good condition otherwise. How can "lump-jaw" be cured—if this is it? Should milk from an affected cow be used?—R. J. T.

This is possibly a case of Actinomycosis which is particularly described as follows:

The disease is generally known among farmers and cattle dealers under the names of "big jaw" and "lump jaw." Attention is first directed to the animal by a swelling, or enlargement of the jaw-bone, and the opinion generally expressed when such a swelling is observed is that the animal has received some severe contusion which has been the starting point of the swelling. The swelling described may effect either the upper or lower jaw, or it may effect both at the same time, and produce considerable swelling of the soft tissues as well as enlargement of the bony structure. The swelling is somewhat painful under pressure and is attached to the bone and the skin. Finally soft areas appear beneath the skin, which break, forming ulcers or the openings of fistulous tracts extending back into the bone and discharging a yellowish, thick pus, which sometimes contains hard yellow granules or fragments of bone. As a result of the swelling described, the molar teeth of the upper and lower jaws may be pushed out of their natural position so that they are no longer in apposition, and they consequently cannot serve the purpose of masticating the food. It may also happen that from destruction of the tooth sockets the teeth drop out. As a result of ulceration it frequenly happens that an opening forms on the external part of the tumor, and frequently a similar destructive process forms as an opening into the mouth itself. Every swelling on the jaw of cattle is to be regarded as possibly actinomycotic if a definite cause for it is not known. In some cases it will be observed that these swellings, after growing for a short time, remain for a time or permanently in a stationary condition. The living parasite, by rapidly reproducing itself, extends through the bony tissue and, by setting up inflammation, causes increase of the swelling. The aim of treatment then, is to destroy the parasite, thereby arresting the growth of the swelling; and this is all that can be done where the utmost success practicable is attained. The importance of early treatment will, however, be understood when it is remembered that there is a continued and rapid multiplication of the parasite, and that this multiplication is attended with increasing damage to the tissues of the animal in which it is lodged.

Treatment.

When there is an external opening on the surface of the swelling, it should be injected with tincture of iodine. When there is no external opening, tincture of iodine may be painted on the skin. This treatment should be applied daily, and may be continued until it is apparent that the growth of the swelling has been checked. The iodine checks the growth of the swelling by destroying the parasite whose continuous development is the means of setting up diseased action in the bone. Internally iodide of potash should be administered in doses of from 2 to 3 drams daily, divided into two doses, and given morning and evening in a pint of warm water. This treatment may be continued for two weeks, when it should be discontinued for ten days, and then repeated if necessary. Other methods have been applied in treating this disease, such as burning the diseased bone with the hot iron, which is said to have proved effectual in checking the progress of the disease.

Should you administer the iodide of potash internally it will probably largely reduce the milk of your cow and at the same time make the milk unfit for use. It will also produce abortion when the cow is well advanced in pregnancy.

The question of use of meat of such animals is generally claimed to be perfectly safe when the disease is in its first stages and located locally.

Mange on Horses.

Horses in Imperial Valley are troubled with mange. Kindly give formula.—R., El Centro.

This disesase is due to irritation of skin caused by microscopic mite of which there are many varieties. So to say that a thorough washing with soap followed by a wash of kresoline and water. We give below a treatment recommended in Diseases of the Horse, issued by the Department of Agriculture, which is doubtless a better remedy:

"The treatment consists in the removal of the scabs by soapsuds and, if necessary, a brush and the thorough application of tobacco 1½ ounces and water 2 pints, prepared by boiling. This may be applied more than once, and should always be repeated after fifteen days, to destroy the new brood that may have been hatched in the interval. All harness and stable utensils should be similarly treated; blankets and rubbers may be boiled, and the stalls should be covered with a white-wash of quick-lime containing one-fourth pound of chloride of lime to the gallon."

Loquat Seed for Stock.

I wish to know if loquat seed, which are about half the bulk of the fruit are a safe stock feed, as the horse cow and pig will eat them like acorn mast.—K.

We have no knowledge of a test of such a food for stock but would imagine no harm would come by it. It will be comparatively easy to make a test using care until results can be observed.

Curl Leaf of Peach.

When is right time to spray for "curl leaf" of peach, and is the lime sulphur and salt the best remedy?—E., Turlock.

When the trees are dormant is the time to spray for curl leaf. The sulphur lime and salt is a good wash but the Bordeaux is better. It should be applied before the spores find lodgment on the leaf, for when once established is hard to kill without killing the tree.

Opening of San Jacinto Forest Reserve.

That we might answer a large number of queries regarding the opening of the San Jacinto Forest Reserve for public entry, we called upon O. R. A. Robinson, receiver and special disbursing agent of the U. S. Land office in Los Angeles. From him we learned:

On July 27 a small part of the San Jacinto Reserve will be thrown open for inspection and one month later, August 27, will be open for entry. These lands were withdrawn and made a part of the San Jacinto Reserve August 23rd, '03 and Oct. 4, '06 and were to be used for forestry purposes. Closer investigation, however, developed the fact that these particular townships were of but little value for forestry. The lands are on the northern and eastern slopes of the reservation, some being almost inaccessible.

All the lands comprise about five townships. For agricultural purposes they have but slight value and from what we learned at the land office, we presume will not attract many farmers who investigate.

Some have also confused the settling of the Yucaipe Valley near Redlands with this forestry reservation. The Yucaipe is said to be a very fine body of land, but is the property of a company which is dividing into parcels and selling to settlers.

From a circular sent out by the Department regarding the San Jacinto and other reserves we quote:

"During the past winter and spring the Forest Service has had a force of men in the field readjusting the boundaries of the National Forests, and in accordance with the policy of the Forest Service all land which is suitable for other purposes is now being excluded.

"Scattered all through the National Forests are many agricultural lands, most small and narrow and more or less isolated so that their elimination is impracticable. Settlement is encouraged in these lands, which are open to homesteaders under the Act of June 11, 1906. This act provides for the homesteading of agricultural lands in the National Forests and is being generally taken advantage of for that purpose. Stockmen and ranchers are not slow in realizing the benefits of residence in National Forests and in many cases petitions have been received by the Forest Service for further extension of their area. This, however, the Service is careful not to do unless it can be shown that the land is chiefly valuable for forest or protection purposes."

Apricot Disease.

What is the matter with my apricot trees? They are two years old and looked fine until they started to leaf out; then they began dying. Some made a growth of six to eight inches and then died. The bark seemed to die on the body first, but on some of the trees only the limbs died. I have about 3000 trees and about 50 of these have died this spring. Most of them are starting from the ground again just above the bud. I lost about 25 trees last year in the same way. They nearly all started from the ground and made a good growth but some of those died this year. I sprayed them last November with Bordeaux. Please let me know what to do with them to save them next year.—J. F. M.

Your trees are suffering from a disease of the sap which causes the sap to ferment. When you prune next winter, do not cut into a healthy tree with the same implement that you have used on a diseased tree without disinfecting it in a solution of bluestone water. We will not say that this precaution will keep the disease from spreading. It is liable to get into the circulation even if you do not go into the orchard, but if you cut into a tree with infected tools, the tree is sure to become infected. That is the only difference. We suggest that you saturate the soil around the base of the trees with a weak solution of bluestone water. This will help to obviate any root infection. These are only suggestions for the exact nature of the disease is not known. There is one consolation, the disease has made its appearance in many places in the south and then utterly disappeared. We think you will have the same experience.

Soft Scale.

We have a Golden Drop Plum tree about four years old with soft brown scale about the size of a lady-bug. They killed one tree last year. What can we do for it?—S. H.

Spray now with kerosine emulsion. This is made by mixing three quarts of kerosene, three pints of water or sour milk and three ounces of soap. Mix with a spray pump till it is a creamy mass. This will make fifteen gallons of emulsion. This formula requires at least fifteen minutes hard pumping to form an emulsion. By using eight times as much soap, it can be made in five minutes and is a better emulsion that is recommended when but a small amount is needed.—J. W. M.

Diabrotica.

I enclose two specimens of lady-bug or beetle that destroys our bean vines, also cucumbers. If you can tell what will destroy them or keep them off the vines will be doing a great favor for this part of the country. They also eat the silk from the sweet corn.—A. V., Acampo.

These are two members of the Diabrotica family. The one with the spots was punctata and the striped one was vittata. They can be conquered by use of the Paris green or better by the arsenati of lead or Disperene spray.

Staking Malagas.

Will the Malaga grape do well without staking, that is, treated the same as the Muscat? —R. L. T.

The Malaga grape is a much stronger grower than the Muscat and should be pruned with at least four buds to the fruiting branch and a spur of one bud at the base. This comes under the head of half long pruning and with the Malaga does not require staking unless the summer growth in your case shows that it requires it. We have pruned them both ways, short and half long, and used no stakes with good results. A weak growing variety, one with slender canes, requires staking with half long pruning.

Eucalyptus and Clover.

By this mail I send you a box containing a sprig of Eucalyptus and also one a species of clover. Please name them for me and oblige.—J. B. S.

The Eucalyptus is Rudis, though to be sure we should see a ripened seed pod. If it is, it is one of our finest Eucalyptus. The clover is sweet clover (Meliotus indica) and a great pest along irrigating ditches and elsewhere.

Powdery Mildew on Apples.

Please tell what to spray with for powdery mildew on apple trees. I have one tree that is affected.—D. C.

Dust with sublimed sulphur. That will act as soon as you have a temperature near 80 degrees.

Legal Queries

Answered by L. M. FALL, Esq.
204 Frost Bldg., Los Angeles, Cal.

Husband and Wife Joining in Deed.

The owner of two lots in the city will sell if I take a deed to same with his signature only. (Lots are record ed in his name.) Would deed be legal? Could his wife or her heirs or assigns claim an interest in those lots? Could a clause be inserted in his deed to bar out above claims?

If it is community property or his separate property his signature is sufficient. The wife has no interest in or power over community property. Her only rights in regard thereto are (a) a right to insist that the husband receive value for any disposition of it which he may make; (b) a right to have certain disposition made of it upon the dissolution of the marital community by divorce or death. While the deed of community property executed by the husband alone may state that a valuable consideration has been received, it is not conclusive and may be disproved by any person in interest. If the wife should claim the property to be community property and prove the statements in the deed to be untrue the purchaser's title would not be good. It is always best for both to join in a deed.

Homestead.

If a man pays a price and only partly pays for it, taking a deed and giving a mortgage can his wife homestead the place if the deed is in his name alone yet both sign the mortgage? Please answer through the Cultivator. S. C.

Yes. A married woman may claim a homestead in (a) community property; (b) her husband's separate property; (c) her separate property. And likewise the husband may claim a homestead, except in case of the wife's separate property she must consent by joining in the declaration of homestead, and in no other manner. The homestead consists of the dwelling-house in which the claimant resides and the land upon which it is situated.

A Difficult Milking Problem Solved

One of the most embarrassing questions confronting the dairymen, especially those on the Pacific Coast, at this time, is that of labor. If it can be secured on any terms, it is more often incompetent, or at least very unsatisfactory. Nothing is harder than to secure a thoroughly trustworthy milker. For this reason dairymen have longed for the perfecting of some mechanical device which would release them from the bondage of incompetent help. As a rule, however, the process of milking has been deemed of such a nature that such mechanical appliance could never be entirely satisfactory; but for the past year or more, reports of various trials with milking machines have been made and the interest has increased and the question is more persistently asked than ever, "But will they be a success?"

One very positive and convincing answer to just that question is now furnished the Cultivator in the letter which follows. This letter was written by practical dairymen, who have given the machine a thorough test of sufficient length of time to know that it will not only work experimentally in the hands of an expert demonstrator, but has accomplished the most satisfactory results in practical everyday work with the ordinary help of the dairy. This letter is dated at Oxnard, California, where, we understand, Messers. Donlon Bros. have found it so satisfactory that, as they say in their letter, "if our machines were destroyed tomorrow we would immediately install a new outfit."

"Replying to yours of the 27th, regarding the milking machines installed in our dairy, beg to advise that the name of the machine is the Burrell-Lawrence-Kennedy Cow Milker and that it is manufactured at Little Falls, N. Y.

"You ask if we are pleased with the machines. If our machines were destroyed by fire or otherwise, we would immediately install a new outfit. We believe this to be as strong a recommendation for the machine as it is possible to give. We further believe that the cow milking question is now practically solved and that it will be only a matter of time when all large dairies will use machines instead of the old hand process.

"The Burrell-Lawrence-Kennedy is very simple. Any man with half a head can operate this machine, even though he has never milked a cow. Each machine milks two cows at the same time, and one man, after a little practice, can easily operate two machines. Our old cows took kindly to them from the start; the heifers kicked quite a bit, but now stand like old cows. The connections with the cow do not in any way hurt her teats and there is absolutely no danger of the machine drawing blood, as some machines do. Another great point of this machine is that we get clean milk, something that nobody can do by the hand process.

"Baker and Hamilton are the sole agents for this machine on the Coast and any information that you may desire about the machine itself can be had from them. We shall be glad to furnish you with any additional information regarding the working of the machine.

"About the clean milking of the machine, we find that they strip the cow clean, if not cleaner, than by the hand process. We get about the same amount of milk now as we did before we started using the machines a month ago and the amount is increasing.

"Trusting this is satisfactory,

"Yours very truly,

(Signed) "DOLAN BROS."

This is surely strong commendation and the advice to write to Baker and Hamilton, if followed, will doubtless bring an interesting answer.

Household Department

IF WE KNEW.

There are gems of wondrous brightness
Ofttimes lying at our feet,
And we pass them, walking thoughtless
Down the busy crowded street;
If we knew, our pace would slacken—
We would step more oft with care,
Lest our careless feet be treading
To the earth some jewel rare.
If we knew what hearts are aching
For the comfort we might bring,
If we knew what souls are yearning
For the sunshine we could fling;
If we knew what feet are weary
Walking pathways roughly laid.
We would quickly hasten forward,
Stretching forth our hands to aid.
If we knew what friends around us
Feel a want they never tell—
That some word we've lightly spoken
Pained and wounded where it fell.
We would speak in accents tender
To each friend we chanced to meet;
We would give to each one freely
Smiles of sympathy so sweet.
—Anon.

TONY'S SEARCH.

POOR little Tony was tired. It seemed to him that the days were much longer in the big American city than they had been in sunny Italy, and he had walked so far today, and played many tunes on his violin. People had been very kind to him and gave him lots of pennies, and the men from his country that he questioned, who were working on the streets and understood him, often shared the contents of their lunch pails with him, after listening to the story of how his father had come some months ago to get work in the big city he had heard so much about, and was going to come home with lots of money. But when he didn't come, Tony had begged of his mother to let him sail with a neighbor who was coming to find work, and would look after Tony all he could.

Tony's mother was very much afraid to have him leave home, too, but he told her he could take his violin, and go around playing, just as old Pierre down in the valley had played on an organ and came back with his monkey jocko all dressed in red velvet and gold trimming. Tony felt sure he could do as well, and then he would surely meet his father somewhere. The anxious mother consented at last, and now he has been so long a time and seemed no nearer finding his father than he was at first. Although he was a plucky little fellow and with all the faith of childhood, he could not help the tears which sometimes overflowed the dark eyes and trickled down the brown cheeks on to his little worn and dusty jacket, but he would not give up the search.

* * *

"Doctor, please come here just a moment," said a white-capped nurse in the accident ward of the hospital. "There is a little boy out on the street playing a violin. There, do you hear him? This patient insists that he be brought in, as he says he is his son, as near as I can understand. What is it, do you suppose; delirum again?" and they both looked critically at the excited man, who begged in his weak voice and broken English to let him see the boy.

The kind hearted doctor looked puzzled, as no one had ever called on this patient, and he did not seem to have any friends, but as he grew more eager with every strain of the music outside, the doctor said:

"Well, it can't be any worse to humor him and let him see the boy than to have him in this state of nervousness." Saying which the doctor stepped to the door and beckoned to the boy to come in.

Wonderingly Tony followed the doctor up the aisle between the rows of cots, tightly clasping his violin. He didn't know what to make of the strange looking place, and the pale faces in the beds almost frightened him. At last, as they were half way down the room, he heard a well-known voice call, "Tony! Tony!" and, looking with bewildered eyes, he saw that he had at last found the dear father he had come so far to seek.

He was clasped in the weak, but uninjured arm of the happy father. The doctor and nurse looked on in wonder as they saw that the patient had not been mistaken after all, as they saw the eloquent eyes of both sparkling in recognition of each other.

How fast Tony and his father talked! Tony told of the mother and the little sister, and of how he had hunted the city streets and was almost in despair of ever finding the father, until fate had led him right to the hospital, where the poor father had lain for months after a huge derrick had fallen on him. He had lingered between life and death, and had become so weak that he could hardly remember anything, until he heard the well-known strains of his little Tony's violin, which had carried him back to dear old Sorrento, the village he loved so well, with its vine-clad hills and the nightingale singing in the orange groves. It seemed to put new life into him; better than medicine, the doctor said.

* * *

When the neighbor returned Tony and his father were with him, and the mother felt that her prayers at her little shrine had not been in vain. Tony thinks more of his violin than ever, as without it he says he never could have succeeded in his search for his father.

IT IS UNUSUAL.

Mark Twain had finished his speech at a recent dinner party, and, on his seating himself, a lawyer rose, shoved his hands deep into his trouser pockets, as was his habit, and laughingly inquired of those present at the society dinner:

"Doesn't it strike this company as a little unusual that a professional humorist should be so funy?"

When the laughter that greeted this sally had subsided, Mark Twain drawled out:

"Doesn't it strike this company as a little unusual that a lawyer should have his hands in his own pockets.

"We've only got a knife or two packed in the basket with the pie. What shall we do?"

"That's all right. Up yonder I think you will find a fork in the road."

HINTS FOR THE COOK.

Fried Bread.

This is a good breakfast dish c for luncheon or supper, and is equall acceptable for children and grow people. Cut the slices nearly a inch thick. Spread with salt por drippings—and turn the spread sid down on a hot frying pan (or "spider as I was taught to call it) over slow fire. When that side is brow turn it over, salt it, turn in three t blespoons of cold water, cover, and l the second side brown. You will neve be able to fry enough for th family, once they have had the app tizing dish as a side relish with othe things.

French Fry.

Beat an egg with a small pinch salt. Add a pint of milk and stir u til well blended. Dip the slices the mixture and fry in a hot "spide with pork drippings.

Tomato Fry.

Prepare in either of the abov ways, and put each slice on a se arate hot plate, turning hot stewe tomatoes over each.

With Cream of Celery.

Prepared either way, serve th slices separately, as above—substitu ing the cream of celery for the tom toes. This is made by mixing flou salt and milk, as for grav and adding finely cut cele that has been boiled until very te der.

With Puree of Peas.

Use split or whole dried peas, pr pared like beans for soup, omi ting the pork. Have this ready pour over the fried bread.

With Scrambled Eggs.

Use milk in scrambling egg and dress the bread with the pre aration.

Under Creamed Hash.

The fried bread should be cut in small squares and laid hot on a h platter, and the hot hash turned ov it.—Mrs. M.

Oatmeal Cookies.

One cup sugar, two-thirds of bu ter or cooking oil, two eggs well-bea en with two tablespoons of mil one cup of chopped raisins, floure one small teaspoon soda, one teaspoo cinnamon, two cups flour, two cup rolled oats. Drop batter from spoo in cake far apart and flatten wit fork dipped in milk or water and bak in quick oven.

Hot Tea Cake.

Beat two eggs to a froth, then ad one-half cup of sugar. Into one cu of sour cream stir one-half teaspoo of soda dissolved in boiling wate add eggs and sugar, with a pinch salt and flour enough to make a sti batter as for griddle cakes. Bake i gem pans and serve hot.

Small Ginger Cakes.

Four tablespoons of sour milk, thre of butter or lard, one beaten egg, on teaspoon each of soda and ginge Put all into a large cup and fill wit molasses. Add sufficient flour t make a stiff batter. Bake in ge pans in a slow oven. Nice war breakfast cakes.

Devil's-Food Cake.

Two cups of brown sugar, 2 egg ½ cup of butter, ½ cup of hot wate ½ cup of sour milk, 1 teaspoon of s da. Dissolve the chocolate and sod in the hot water. Use flour enoug to make batter for layer-cake.

Filling: Boil until it gets quit

thick, 1½ cups of brown sugar, one-third cup of butter and ½ cup of hot water.

Orange Sago.

One cup sago, two cups cold water, three cups orange juice, equal to the juice of about twelve oranges, two cups sugar, pinch of salt. Wash sago well. Soak in the water two hours. Add orange juice, sugar and salt and boil in a porcelain vessel until sago is clear. Turn into a bowl which has been rinsed in cold water then it will turn out easily. Serve with sweet cream or a delicate boiled custard.

DONT'S FOR BOYS AND GIRLS.

Boys.

Don't wear your hat in the house.

Don't sit while a caller stands.

Don't get into the habit of using slang. Vulgar expressions denote degeneracy.

Don't be ashamed of gallantry toward women and girls. A gentleman is always courteous toward the opposite sex.

Don't fall into bad habits with the fixed intention of "swearing off" as you grow older. Habits formed in youth accompany one to the grave, bad habits often burying their victims before their time.

Don't speak of your father as "the goyernor," nor of your mother as "the madam." If you do not show respect to your parents you must not look to the world to respect you.

Girls.

Don't be rude toward your brothers. Boy's feelings are as sensitive as girls.'

Don't forget to give as much respect and obedience to your father that you do to your mother. Often the rightful head of the house is placed at the foot through sheer thoughtlessness on the part of his family.

Don't forget that it is in most cases it is the father who devotes his life in work and worry to provide for his family, and show him the gratitude he deserves.

Don't have secrets from your mother. Remember that she was a girl once like yourself, and that she will prove the most sympathetic confidant in the world, or she holds your happiness and welfare at heart.

SUGGESSTIVE FRENCH PROVERBS.

To the hungry no bread is bad.

A cheap bargain takes money from the purse.

From the hand to the mouth the soup is often lost.

Do not speak of a rope in the house of one who was hanged.

You will never buy cheap if you don't ask the price.

Decency is the genuine tint of virtue, and the disguise of vice.

Love and smoke cannot be hidden.

The cost takes away the taste.

A sparrow in the hand is better than a goose on the wing.

'Tis a hard winter when one wolf eats another.

If the sky falls we shall catch larks.

Our minds are as different as our faces; we are all traveling to one destination—happiness; but few are going by the same road.—Machiavelli.

"What a bright little thing!" exclaimed the society woman, patronizingly cooing at a baby out for an airing in the park. "Whose little one is this?"

"Yours, ma'am," replied the nurse. "I'm the new nurse that kem yisterd'y"—Philadelphia Press.

ONCE UPON A TIME.

Heard I once my old nurse telling
Stories by the fire at night,
All about big, bearder giants
Till I shivered in affright;
Then her voice came from a distance
From a drowsy, far-off clime,
Echoing the sweet old cadence,
"Once upon a Time."

Read I once a golden story
Of King Arthur's wonder court,
Lancelot and Guinevere,
All the knights of brave report.
But amidst the loving, hating,
Still I heard the insistent chime,
Like a cuckoo clock repeating,
"Once upon a Time."

Will our lives when we have lived them
Seem like stories we have read?
Stories which our nurses told us
As we lay all snug in bed?
Will they seem as vague as dreams are,
All the days we thought sublime?
Shall we hear the faint, low whisper,
"Once upon a Time."

When the earth and day and sunlight
Grayly fade away,
When the years that we have lived here
Seem like one brief day;
Shall we hear again at twilight
Echo of our nurse's rhyme,
"Here you lived and loved and labored,"
"Once upon a Time."

—Selected.

MISTAKES IN MAXIMS.

Virtue is its only reward.

The wages of sin is debt.

Policy is the best honesty.

A pitch in time saves nine.

Many hands like light work.

Osculation is the thief of time.

A bird in the hand lays no eggs.

Every dogma must have its day.

A thirsty man will catch at a straw.

The woman who collaborates is lost.

It is not good for a man to give a loan.

Straws show which way the gin goes.

The rolling stone catches the worm.

Absinthe makes the heart grow fonder.

The lack of money is the root of all evil.

It's a wise child that owes his own father.

A man is known by the trumpery he keeps.

Where wisdom is bliss it is folly to be ignorant.

All that a man hath will he give to his wife.

NOT THE HISTORIC FORT.

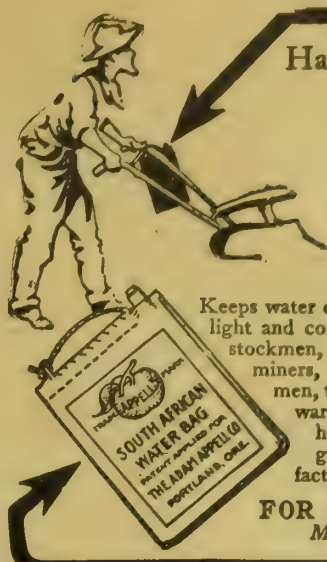
The Sutter's fort reported to have been swept away in the flood is not the historic but primitive fortification erected by Captain John A. Sutter where Sacramento now stands, and which was the arrival point of the swarm of gold seekers coming across the plains in 1849. That ancient adobe fortress has been restored and is now the property of the State. A flood sufficient to destroy it would overwhelm the city of Sacramento. The fort washed away was a small portable iron entrenchment made in Europe and shipped out here in sections by Captain Sutter. It was situated on the mound near Marysville, and was of no value and little interest, as it was never associated with any historical event.

Jigley—We were talking about suburban cottages, and Subbubs remarked that the only thing they ever dreamed of out his way in Boghurst was Queen Anne.

Citiman—The idea! Is that the way he pronounces it now?

Jigley—Prouonuces what?

Citiman—Quinine.—The Philadelphia Press.



Have a cool drink—with you any time

APPELL'S
SOUTH AFRICAN
WATER BAG
(PATENT APPLIED FOR)

Keeps water cool 48 hours or longer; in sun or shade; no ice; light and convenient to carry. It is a great boon to farmers, stockmen, rangers, travelers, prospectors, surveyors, sportsmen, miners, timbermen, threshing crews, millmen, railroad men, teamsters, boatmen and everyone exposed to dry or warm weather, away from good water supply. Can be hung on vehicle, implement, or tree, or laid on the ground—anywhere so it is exposed to the air. Satisfaction guaranteed or money back.

WANTED—SOME APPLIANCE FOR MOVing full-grown lemon trees. A. Z. TAFT. Hollywood, Cal.

The new map of California, issued by the California Promotion Committee, is just off the press. It has been carried quite up-to-date and shows the many recent developments in railroads, steamship routes, pipe lines, etc. In addition to the map itself there are given a full complement of the latest and reliable statistics concerning the cities and their population, and the agricultural, mineral, horticultural and manufacturing resources of the State.

The Produce Markets

Los Angeles Markets

LOS ANGELES, June 5.

Large supplies meeting a good demand seems to be the satisfactory condition of the market this week. Eggs commanded the most interest and the rivalry to purchase has boosted the price a couple of cents over last week's quotation.

Butter.

Butter shows a slight advance though the receipts are heavy, more so than at corresponding date last year.

Creamery extra	55
Creamery first	52½
Dairy	22½

Cheese.

Cal. Young American, per lb	19
California Anchor	18
Cal 3-lb. hand	20
Northern fresh	15¾
Domestic Swiss	18½
Imported Swiss	30

Eggs and Poultry.

Northern eggs are yet weak but local candled are sought for so that prices advance nearly every day. As long as the market is cleaned up as it is now the price will hold firm and advance.

The prices given are those of the commission man to the retailer.

Eggs, local, candled	23
Eggs, case count	21
Eggs northern	17

The following are average prices which dealers pay to producers for live weight:

Hens, per lb	13
Young Roosters, per lb	17
Fryers	20
Broilers, per lb	26
Old Roosters	7
Turkeys	17
Geese	12
Ducks	13
Squabs per doz	1.50@1.75

Live Stock.

The following quotations are f. o. b., Los Angeles, on all stock.

Hogs, 200 lbs	7.50@8.00
Prime Steers	4¾
Heifers	4¼
Calves per lb	5
Sheep, ewes, per head	5.00@5.25
Lambs per head	4@4.25
Wethers	5.50

Potatoes.

Potatoes are firm and some dealers report they are getting half a cent more than a week ago on fancy new crop.

Colorado	2.00

Eggs and Poultry.

Eggs are in keen demand with a materially higher price than last week. Still stronger market anticipated.

Fresh Ranch Eggs	20
Eggs, first, per doz	18½
Eggs, seconds, per doz	17
Eggs, thirds	16

A goodly portion of last week's stock of poultry was left over, which will doubtless cause the market to be heavily supplied for several days to come. A decidedly improved business in Eastern grades is anticipated the last half of the week. California stock meets with hardly and demand whatsoever and all resonable offers on both this and Eastern varieties are for the present readily accepted.

Wheat, No. 2	13@17

Grain.

Strictly choice wheat is very scarce and what stock there is appears to be closely held in few hands. The millers are not particularly short of supplies, but they are buying wherever and whenever they can pick up any desirable stock suitable for milling purposes. The local market for barley continues somewhat depressed and even the recently reduced figures are inclined toward weakness. Supplies are not heavy and, in fact, the quantity available in this city and nearby places is considerably less than at this time in May.

Citrus Market

LOS ANGELES, June 5, 1907.

Oranges are going out at this writing at a very rapid rate. The daily shipments are now 50 per cent greater than last year at this time. With it all, a fairly good price prevails. This condition is aided by the weather which has been friendly to oranges, more so than to lemons. The cool weather has kept the fruit in good condition and it has made a fine appearance on the market. If hot weather should be bestowed upon us soon it will cause poor keeping qualities and drive people to lemons. Meantime navels are being cleaned up, only 200 or 300 cars now remaining in California. Another week or ten days will see them all gone. Sweets, Mikes and Seedlings make the bulk of shipments at this time.

Lemons.

Lemons are quiet. They are longing for the frosty weather and other Eastern freakishness to cease. Foreigns are still coming and still selling at a price that is "handing the lemon" to importers. Californias are receiving better attention than foreigns, however, and satisfy the trade which demands it. Phices will rise with the temperature and a good season is promised.

Shipments.

Shipments to date aggregate 21,678 cars of which 2,078 were lemons. To same date last season, 21,478 and 2,451.

NEW YORK, June 3.—The market continues very strong. Forty-six carloads of oranges and one carload of lemons sold today.

SORE SHOULDERS.

At this season of the year a good many horses are troubled with sore shoulders, necks and backs. It is not surprising as a horse goes into hard work after a winter of comparative idleness, and it is easy to get him out of shape notwithstanding that you take good care of him all the time. A remedy for this very thing will be found in the Security Gall Salve, made by the Security Remedy Company, of Minneapolis, Minn. They claim for this salve that one application will relieve pain from the most severe sores and that it will heal and cure them. This company also makes an antiseptic healer for barb wire cuts which will cure the cuts very quickly. They would like to send a free sample to California Cultivator readers, of their Gall Salve, and authorize us to make the offer, the only condition being that those who ask for the free sample mention the paper when writing. If you have horses that are troubled with sore shoulders or necks don't fail to write them at once, mentioning the paper.

NURSERYMAN HAS A TREE DAY.

J. B. Wagner is original; also grows some original things and sells them. Recently the idea came to him to present everybody a tree. So he advertised that every one who would call at his Pasadena salesyard should have a tree for the asking. He knew advertising paid but when the 3500 people, which he says came, rolled in on him he was surprised, but stood his ground and made good to every caller and Pasadena cars were filled with people lugging trees of all kinds.

Mr. Wagner has supplied several school grounds and public parks with trees without cost.

It is possible he has also sold some trees for we note that he takes an extended Eastern trip this season.

COST OF IRRIGATING.

"There are three essentials to successful farming: Fertile soil, intelligent labor and water in abundance. The first two you have. You do not control the weather. If you did you could double your crop but you might be unpopular. You are no rainmaker. Yet easily and inexpensively you can supplement the rainfall, as far as your land is concerned, from an unfailing water supply."

The above is from a little booklet issued by the American Well Works, Aurora, Illinois, and is the preface of a fund of information which is invaluable to the irrigator. Especial reference is made to cost of lifting water and so much information is packed in the few pages that it is well worth sending for.

If you mention the Cultivator we think it will be mailed without cost.

IT'S PENNY WISE.

Policy to set out a good tree, costing good money and then let the sun burn the bark or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Manufacturing Company, 2124 Willow St., Los Angeles.

THE CHATHAM FANNING MILL

WITH BAGGING ATTACHMENT will clean and grade any kind of grain, taking wild oats, cockle, and wild radish seeds from wheat or barley; cleaning and grading oats, cleaning beans, peas and any kind of clover or timothy seed. The Walnut Growers' Institute

A Most Interesting Meeting, with Valuable Discussions on Blight, Cultivation, Irrigation, Cover Crops, and Other Matters of Interest

With Notes by PROF. R. E. SMITH

THE meeting of walnut growers held at Whittier on June 5th and 6th, may be said to have marked an epoch in the history of this industry. The attendance of over 200 growers from every walnut producing section of the State, the earnestness and sustained interest of the discussions, and the generally business-like, serious and straight-to-the-point air of the whole meeting could not fail to impress one familiar with California walnut growing that a long step forward in the progress of the industry will result from this meeting.

Can We Stop the Blight.

The basis underlying most of the discussions, and in fact the original cause of the meeting itself, was walnut blight, the disease which is looked upon as the one great obstacle to walnut culture. Yet, in spite of the acknowledged seriousness of this trouble and the lack of any definite remedial treatment to check its ravages, the pronounced trend of feeling among the growers present was very strongly along two lines:

First, that the walnut industry is by no means crippled or in danger of extermination, but on the contrary is one of the most profitable and promising horticultural industries of the State; second, that the blight is only one of many causes of diminished production, chief among which is a lack of the best methods of intensive culture.

Most noticeable and encouraging of all was the trend of thought of the whole meeting and of every speaker, toward the necessity of better culture, the need of a more extensive and intelligent use of fertilizers and cover crops, the demand for standard and more satisfactory varieties, and the indication in every way that the industry has left the happy-go-lucky, care-free, bonanza stage, and is entering the class of a high-grade horticultural production, with standard, definite established methods and results.

Cover Crops.

The convention opened on Wednesday morning, June 5th, with J. B. Neff, conductor of Farmers' Institute for the University of California, in the chair. Dr. J. A. Osmun, of Whittier, introduced the discussions in a practical way by describing his own experiences in walnut growing and avowing his unbounded faith in the future of the industry. This speaker had found that by the use of cover crops and systematic culture and care, the production of his trees could be largely increased in spite of the blight, and the disease had largely lost its terrors for him.

Fertilization.

The subject of Fertilization of Walnut trees was discussed at length by Thos. Gooch, of Rivera; Ralph McNees, of Whittier and H. E. Collins, of Rivera, as well as many of the audience. The condition of the industry in this particular was made very plain by all these speakers; namely, that the time has come when fertilization of some sort must be resorted to, but that little is known at present as to definite methods or requirements. The use of cover crops was strongly endorsed, and the fact brought out that the growing of such crops in walnut orchards is becoming very general. Peas had been most largely grown, but a tendency in favor of vetch was quite general.

Scientific Work.

The subject of The Practical Value of Scientific Work in the Prevention of Plant Diseases, was handled by Mr. H. J. Ramsey, of the Southern California Pathological Laboratory, in the absence of Prof. E. J. Wickson, who had been expected to be present and speak on this subject. The speaker showed the great practical benefit which horticulture has received in many different ways from scientific research. Mr. E. S. Ware, of Garden Grove, described the rather unpromising results of a long and very carefully conducted series of experiments in the control of walnut blight, especially with the use of Bordeaux mixture. He saw the ultimate solution of the blight problem in the development of immune varieties, an achievement which was already advanced, but urged more complete and thorough investigation of the disease, looking toward a satisfactory method of treatment for the control of the disease in the present orchards. He had found some benefit from the applications of lime to the soil.

Irrigation and Cultivation.

Wednesday afternoon the subject of Irrigation and Cultivation of Walnuts, was discussed by P. F. Cogswell, of El Monte; B. F. Porter, of Fullerton and C. S. Sanderson, of Whittier. The question of the best time for irrigation of walnut trees provoked much discussion and difference of opinion, bringing out a mass of the contradictory experience and opinions which is typical of walnut culture.

The relation of irrigation to "Die Back" was given particular prominence. The fact was considered as established that die back is an effect of climatic and soil conditions, related especially to moisture and temperature. When local conditions and extreme opinions had been allowed for and modified, the practice of heavy winter irrigation appeared to be most in favor under average conditions in Southern California, flooding the ground heavily in January, February or March without much regard to the amount of rainfall. Additional irrigation in June and August found favor with most of the growers, and many believed in still further wetting the ground after finishing the harvest. Most stress was laid on the application in winter of a large amount of water. The furrow-system of application was generally considered most satisfactory.

Walnut Industry Will Prosper.

The speakers of Wednesday evening were F. E. Kellogg, of Goleta, and C. C. Teague, of Santa Paula. Both speakers expressed their substantial faith in the walnut industry and it's future. Mr. Kellogg believed in planting the trees further apart than has been the practice, a view shared by most of those present, advocating a distance of 60, 70 or even 80 feet in squares, planting also a tree in the centre of the square to be taken out as soon as the branches began to touch.

He advised winter irrigation, plenty of fertilizer and the removal of blighted twigs and nuts so far as practical. "Above all," said Mr. Kellogg, "Let me say that the walnut blight does not mean the extermination of the walnut industry or the ruin of our growers. Blight or no blight, the walnut industry is today one of the most prosperous and one of the most hopeful horticultural industries of Southern California." Mr. Teague expressed an idea which was generally concurred in, that the trees which come out latest in the spring are the least affected by blight, and suggested the possibility of maintaining a growth late in the fall and corresponding late coming out in the spring, by means of irrigation. He saw a great future in the growing of the walnut in California, and had confidence that all problems and difficulties would be met, as they always have been in other similar cases.

A general expression of opinion was called for as to the comparative merits of the seedling and grafted tree. Considerable discussion followed, in which the opinion was almost unanimous in favor of the latter.

Possibilities of Improvement.

On Thursday morning Mr. L. B. Hogue, of Santa Paula, called attention to the variation in seedling trees in respect to productiveness and quality as well as blight resistance, and suggested the possibility of breeding up an improved variety by successive selection and planting of nuts from the best trees in each generation.

Prof. Smith Says Sprays Don't Pay.

Prof. R. E. Smith followed, on the Experimental Work on Walnuts of the Southern California Pathological Laboratory. Extensive spraying experiments with Bordeaux mixture, lime salt and sulphur and other fungicides had given very unpromising results. The same was true regarding "dust spray." As a result of all his experiences and observations the speaker had come to the conclusion that very little was to be hoped from spraying by any method, on account of the expense and impracticability of the operation on walnut trees. Under the head of cultural methods the use of fertilizers and better culture were discussed. In this direction there seemed to be much promise, and experiments were being conducted by the laboratory on a considerable acreage of walnuts in the use of different fertilizers and combinations.

The speaker believed that if we must lose a certain per centage of nuts by blight, it is certainly better to lose it on 200 or 300 pounds per tree than on 30 or 40. Blight treatment might save the affected nuts, but only good culture can increase the actual crop which the tree sets, and in this direction there are greater possibilities of increasing the crop than in blight control.

Blight Resisters.

Special emphasis was laid on the prospects of securing blight-resistant varieties and the practicability of re-forming the industry along such lines. The speaker believed that the day of the grafted tree had come and that the general planting of seedlings was a thing of the past. The best variety or varieties might not have yet been found, but as a general proposition the seedling grove was doomed to be superseded by grafted trees. The best seedling might be good enough, but the average one was not. The grafted tree makes it possible to have the average as good as the best. The different varieties

Deciduous Fruit Culture

WALNUTS.

IT WAS one time thought that the overproduction of walnuts in California would soon be realized, but from various causes it has proven a false conjecture, just as the hue and cry of overproduction of oranges was once sounded.

The falling off in production is no doubt due to a number of causes, but the chief cause is no doubt due to the blight. We have often been asked which is the best variety to plant. Taking all things into consideration, this is a hard question to answer. There are one or two varieties that are practically free from blight, but so far as known, they are not prolific bearers in Southern California. Were this not the case, there would be no doubt what variety to plant. There may be some varieties brought out in the near future that will give entire satisfaction. At present, the most widely tested variety that is in the lead is Placentia Perfection. It is not blight-proof, in fact, is very susceptible to blight during the early life of the tree, due to its rank growth. It is known that disease that works through the sap, works most rapidly when the sap is flowing most freely. The Placentia nut thus affords a good chance for the development of blight, but it is only during the early growth of the tree. As a prominent grower once remarked, "I would not think of planting a variety that was not a good grower, even if it did not get set back with the blight."

The tree that is naturally a rapid grower will in the long run make the best tree.

One way to lessen the ravages of the blight is to plant the trees a long way apart. It is quite well known that old groves of large trees are more badly affected than are young groves. The latter get the most sunlight and this is undoubtedly the reason. Where there is abundant sunshine all during the early spring growth of trees and nuts, the blight does less damage than when the weather is cloudy and damp. This is evidenced during seasons of abnormal sunshine and with late blooming varieties. Herein lies the key to the most practical solution of the blight question. When some variety is developed that will not put out its leaves and blossoms till the season favoring the development of the blight is past, then we will have disposed of the present form of blight.

Fortunately, the walnut is capable of being grafted, even when quite old, making possible the conversion of large areas of walnut trees when such a nut is developed. This is not a groundless hope, but one very likely and without doubt a sure development. The fact that varieties now exist that lack but one requirement, that of productivness, shows what is coming. In the meantime plant that variety which produces the most merchantable nut in paying quantities.

FERTILIZING WALNUTS.

I am a walnut grower and interested in the manufacture of commercial fertilizers. A combination that one would naturally suppose would put me in a position to give light on this subject. I and a few other men I know are fertilizing our groves with some success, but I have not yet determined enought to say to you, do this or do that. However, I have determined this much: that you must fertilize your trees if you expect to keep up the yield to a paying basis. Why a man should fertilize his orange grove, lemon grove or truck patch and stop short on his walnut grove I cannot see.

Return What You Borrow.

If you can produce a good crop this bogie man, the walnut disease, will have very little terror for you. You are removing from 500 pounds to 2000 pounds of nuts per acre per year and the constituents of the crop must be returned, or sooner or later exhaustion of the soil will result. A thousand pounds of nuts removes from the soil 8.18 pounds of potash; 1.56 pounds of lime; 1.47 pounds of phosphhoric acid and 5.41 pounds of nitrogen. You cannot rotate your walnut crop and relieve the pressure so to speak that way, therefore you must return the plant food sold off in the crop by commercial fertilizers, adapting the formula to your specific soil and conditions, supplying the humus by stable manure or cover crop.

Stop one minute and consider why it is that one piece of land will produce more nuts per acre than another; this condition may exist and often does in one man's grove; the reason for this is that the piece of soil that produces the most nuts has those elements of nitrogen, phosphoric acid and potash in abundance and in the forms best suited to produce large crops; whereas, the other piece is deficient in these elements, therefore less crop is the result; is not this conclusive evidence that fertilization is necessary.

Smith All Right.

Prof. Smith, of Whittier, who is doing excellent work towards solving the walnut problem, said to me about the "disease." The remedy lies at the roots of the trees; produce more nuts, then you will notice the disease less. Notice again the outside row of your groves where they have plenty of room to feed and, as a rule, plenty of food, and you will see more nuts per tree; again, a lone tree will yield phenomenally, taking into consideration light and air as imparted-factors; yet at the same time we must credit the amount of food with some of the results.

Don't Worry.

Do not get discouraged about the walnut business. I have seen groves that had plenty of "dead tips" brought back to their pristine condition with fertilizer. Do not look for immediate results; remember the nuts you will harvest in the fall of 1908 are now in an embryonic state and have been since the trees first started to make wood this spring. Unlike an orange that makes a blossom or fruit growth in the spring on wood made the preceeding summer, the walnut makes its fruit buds for next year this spring, therefore give your fertilizer, whatever it is, a chance; remember fertilizer in the ground is not in the tree, it takes time for the process of absorption and dissemination through the tree structure to take place.

Watch Them Grow.

I would not plant trees closer than 50 feet, many advocate even 60 or 70. Fertilize and study your soil and tree growth. What might prove beneficial for you might not give your neighbor such good results. Get your fertiizer on early in December if possible. Keep it up like you do on other crops and you will say there is money in walnuts at one ton per acre.—H. E. Collins before Walnut Growers' Institute.

EUREKA HARNESS OIL

Makes harness proof against heat and moisture. Gives a glossy black finish. Prevents rot. Imparts pliability, strength and durability to leather. Saves bills and mishaps. General Agriculture

OUR MOST DESTRUCTIVE RODENT.

THE U. S. Department of Agriculture will soon issue Farmers' Bulletin 297, entitled "Methods of Destroying Rats," prepared, under the supervision of the Chief of the Bureau of Biological Survey, by D. E. Lantz, Assistant Biologist. The topic is of perennial interest, and an infallible method of exterminating these rodents would be worth more to the people of the United States in a single decade than the Department of Agriculture has cost since its establishment.

One rat is much like another so far as destructiveness goes, but it is of interest to note that three kinds have appeared in this country, all immigrants from the Old World. The black rat was the first to reach our shores, which it did nearly three hundred years ago. The common species, known as the brown, or Norway, rat, arrived about the year 1775 and at once proceeded to drive out its weaker rival, until almost everywhere it has supplanted it. The third species, known as the roof, or Alexandrine, rat of Egypt, is a great mariner and infests every ship; hence, naturally it is common along our coast, especially in the South.

All rats are dangerous foes, but the brown rat is the worst mammalian pest in existence and in the United States destroys more property than all other noxious animals combined. No statistics of the actual damage annually done by these rodents have been gathered in America. In Denmark the loss is put at $3.000,000 a year, and in France the damage by both rats and mice has been estimated at $40,000,000 annually. A single rat will consume about 2 ounces of wheat or corn a day, and it destroys far more of the latter than it eats, as indeed it does of most other food. The average cost to the country of feeding a rat on grain is about 50 cents a year. If for each cow, horse, sheep and hog on the farms of the United States the farmers support one rat on grain, the toll levied on the cereals by these rodents would reach the enormous total of $100,000,000 a year. Even granting that half their food is waste material, the tax of feeding rats is still an enormous drain on the profits of agriculture.

But much of their food is more expensive than grain, and the actual losses due to these animals are by no means confined to food. They enter stores and warehouses and destroy dry goods—lace curtains, carpets, woolens, silks—as well as kid gloves and other leather goods. They gnaw through lead pipes, flooding buildings with water or filling them with gas. They injure furniture and the foundations and doors of buildings. They eat the insulation from electric wires, thus causing diastrous fires. The average fire loss in the United States due to defective insulation is placed at $15,000,000 annually, a considarable part of which is said to be caused by rats.

Rats destroy eggs and young poultry, pigeons, game birds and wild song birds. They have been known to kill young rabbits, pigs and lambs, and even to attack children. Carl Hagenbeck once lost three young elephants because rats gnawed their feet, inflicting incurable wounds.

In addition to the direct damage they do, rats are known to be active agents in carrying disease germs from house to house and from city to city. Bubonic plague is usuallly disseminated from port to port in this way.

Their prolificness is the chief obstacle to their extermination. They produce young from three to six times a year, and females breed from about three months old. The average litter is about ten, but often it numbers fourteen or more. If three litters of ten each are produced every year, a single pair, breding without check and without losses by death, in three years would be represented by ten generations and would number 20,1ɔɔ,392 individuals. The eleventh generation, due at the beginning of the fourth year, would number over a hundred millions.

The world has been fighting rats for several centuries, but the warfare has been neither systematic nor persistent. The number of "infallible" devices and formulas for killing the rodents that have been put forth would fill volumes, and still the pestiferious rat survives and grows more and more cunning as the devices for its destruction gain in ingenuity.

The Biological Survey does not pretend to have worked out an infallible device for killing rats by wholesale, but the methods for their destruction given in the bulletin are those which careful experiments have shown to be the best, and the formulas for poisoning and trapping are the most approved ones. Particular emphasis is placed on the rat-proof construction of buildings and on organized co-operative efforts to destroy the animals.

The bulletin will be furnished free upon application to the United States Department of Agriculture or to Senators, Representatives and Delegates in Congress.

VERMONT'S CROP OF MAPLE SUGAR.

The National pure food law is working wonders for the maple sugar producers, acting largely as it does as a guarantee of the purity of the products offered as genuine maple sugar and syrup. Vermont is the chief sugar-producer, and it is estimated that in that State the total output will reach 20 millions of pounds of sugar and syrup combined. The general price for the genuine article during the last few years has been from 8 to 12 cents; and now, with the increased demand for it, owing to the probable purity of all that is offered, the crop is bringing from 15 to 20 cents per pound. At 15 cents per pound the maple sugar crop of Vermont will amount to about three millions of dollars in value.

ROAD-MAKING IMPLEMENTS.

State Engineer Nathaniel Ellery has consented to conduct an exhibition of practical road making at the Fair Grounds for the benefit of Supervisors, Roadmasters, and others interested during the next State Fair, Sept. 2, 1907, and anticipating that manufacturers of the necessary implements will be glad to supply the same and help to operate them, as they do for these exhibitions in the Eastern States, the Society offers special prizes for such implements in operation.

The Farmers' Institute at Pomona will be held June 28 and 29.

The Government Makes Butter

ALBERTA, Canada, is one of the best dairying countries in the world.

The Government has done everything possible to encourage the dairying industry, and the result is that hundreds of dairy farmers are getting rich at the business.

In order to stop abuses and insure a steady market and favorable market conditions for the dairy farmer the Alberta Government has established numerous creameries. These creameries are conducted on the most economical plan, and the cost of producing and marketing butter has been reduced far below the cost to private concerns.

The farmer takes his butter fat to the Government creamery and receives ten cents a pound down upon delivery. As soon as the fat has been turned into butter and sold he receives the balance due, after four cents a pound has been deducted by the Government to pay the cost of producing and marketing the butter.

Of course, if any farmer or any private company desires to make butter there are no restrictions, but the Government can do the work so much better and for so much less cost that it pays no one to try to compete.

Dairying is only one of the lines that can be made profitable to the farmer.

Alberta is the best live stock country on the American continent. It is also a great cereal country, and all kinds of vegetables can be raised there.

The great irrigation project now under way near Calgary is destined to increase the production of the naturally rich soil many hundred per cent. Land under this great ditch will afford ideal farming conditions. If the farmer wants to raise live stock as well as crops of all kinds, grazing land can be secured in connection with irrigated land, and these combination farms will permit of diversified farming that is very profitable.

The man who is looking for a new location or an investment cannot do better than to visit Sunny Southern Alberta. Full information as to how to make the trip at very small cost, how to secure as good land as lies out of doors very cheap, and on the easiest of terms, will be sent upon application to

Lost Strayed or Stolen—One Cow

That is about what happens each year for the man who owns five cows and does not use a **Tubular** cream separator. He loses in cream more than the price of a good cow. The more cows he owns the greater the loss. This is a fact on which Agricultural Colleges, Dairy Experts and the best Dairymen all agree, and so do you if you use a **Tubular.** If not, it's high time you

did. You can't afford to lose the price of one or more cows each year—there's no reason why you should. Get a **Tubular** and get more and better cream out of the milk; save time and labor and have warm sweet skimmed milk for the calves. Don't buy some cheap rattle-trap thing called a separator; that won't do any good. You need a real skimmer that does perfect work, skims clean, thick or thin, hot or cold; runs easy; simple in construction; easily understood. That's the **Tubular** and there is but one **Tubular,** the **Sharples Tubular.** Don't you want our little book "Business Dairymen," and our Catalog A. 260 both free? A postal will bring them.

CALIFORNIA DAIRYING.

[The following is an address given by Mrs. Sherman at the recent Farmers' Institute and Basket picnic, held at the California Polytechnic School, San Luis, Obispo. It contains so much that is good that we give it this week in place of her regular article.—Ed.]

TODAY is a play day, a picnic, the best work we do is our play; when we play we are learning rapidly the joy of being with our fellow men. It is the union of minds that strength comes, so that in the anticipation of pleasure we grow in strength. Now if you will rise to the fact that the only happy people in the world are those that work; their hearts are full of joy, of light-hearted joy, then we may make the most of this day together and all go home believing in sympathy as the key to knowledge and the open door to all hearts.

The Country.

God made California a wonderful country; the blue of the skies is more intensely scintillating blue than other skies. The mountains are high and fringed with foothills that in other countries would be called mountains. Great valleys are irrigated with snow-fed rivers. These valleys have only lately been redeemed from dryness, indeed, much of the San Joaquin was considered desert land. This land has been redeemed from aridity by the utilizing of the water that used to run in great floods to the sea. The beauty of the wild flowers that carpet the plains in the springtime has been made an all-year-fiesta by the gardens of the horticulturist. In truth, the desert now blooms like a rose. The effect of all this beauty is showing on the children, on the home life and it has touched the dairyman until he is thinking of improved stock and of making his barns and corrals neat. He is desiring to have his cows a credit to him rather than something he hopes the neighbors will not see as they pass on the road.

Ideal Life.

In California the ideal life will some day become the natural life when we are wise enough to stop and live, instead of constantly rushing and grasping for money. When we come close to Nature for knowledge, this will be the home for poets and thinkers. It is the destiny of the people to develop a high civilization on the Pacific Coast. The dreamy plains with the clear starlight nights and long, bright days, turn the thoughts toward Diety, while on the coast the restless sea that booms and breaks eternally, awes with its resistless powers.

The gloomy fastness of the mountain heights and great depths of the canyons all are sources of wonder to the mind trained to appreciation. I have impressed with the resistance of the mind to adverse conditions in the unattractive homes of the children of our foreign classes. They become apathetic and have to be aroused to the knowledge that flowers will grow anywhere and that vines will clamber as gracefully over a rough board shack as over the finest of pergolas.

When we are conscious that our surroundings are as we make them—beautiful or folorn, it becomes apparent that we must make our work our happiness or we will never have any in this world.

Character of Country.

The coast lands of California are broken by few bays; it is a land of little frost and is well-watered by rain in the winter and in the summer the cool, soft gray mist drifts in from the ocean. The interior valleys are cooler in the winter and warmer in the summer. They have distinct seasons. Yes, they are sunny in the summer with a soft, dry heat that is delightful. The foothills are full of good grazing during the wet season. Then they become parched from the pitiless sun beating on them and the reflection from the mountains that tower over them.

Surely, in all this range of country with its varying natural feeds there is room for every breed of dairy cows! The cow is naturally at her best in the most home-like surroundings. Dairy cattle are man made and all have been made to produce by selection of the best individuals from generation to generation.

Breed and Feed.

Breeding is of great value at first. Later, feeding becomes equally as great. It is the man's business to grow and to feed that which his land will produce in the largest measure. The home of the cow really expresses the conditions better than the word environments. Now we can improve the cow's home as much as we improve our own; the cow needs shelter during the rain storms as much as we do. She needs to be fed regularly when not on good pasture. She needs to be milked at regular hours. She needs to be kept clean, free from lice and ticks and to make milk fit for human use; she should be kept from manure. She should have fresh water and wholesome food. Put yourself in the cow's place and make her bed sweet as your own and her feed and water as perfect.

Which, then, is the greater, the surroundings of the dairy herd or its blood lines? I do not know. Take the finest dairy cows in the world and under scrub conditions and in ten years they will become degenerated. Take scrub cows feed them liberally and they respond to a certain limit at once. Take pure-bred stock that is run down and they can be brought back in a couple of generations to better things. But I would rather not have to do it.

Tersely put, the successful dairyman wants dairy-bred cows, good feed and best of conditions and he will have financial success.

Failures.

There would be fewer failures if the conditions of animal life were better understood. The wise way is to experiment and prove in a small way before going into it in a larger way. The dairyman that does not love cows had best stop dairying at once for he is merely a drag on the industry.

There are born failures that should never work for themselves but always be under others' directions. If you have been one of them people take the little word "now" for a mot-

to and stop being a failure at once. "Failure is a habit—ask any banker! Guarding against disaster is a habit, as much as getting drunk." Success is in the blood of the successful master as well as in the blood of the cows.

Diversity of Breeds.

What is a breed? It is a race of animals made by the selection along the desired lines for generations, by carefully mating the animals that have the desired qualities, and weeding out those that are not up to the standard of or true to the type that the breeder has in his mind. Not only must the qualities be in the individual; they must be so fixed that they will be transmitted every time when mated with an animal of equal excellence. The calves of the best cows are selected each time and the physically perfect and strong only are raised. Then the strain is improved. The old way was to aim at nothing in particular, beyond the individual cow, so that the calves were raised, registered and passed out, whether worthless or not. The advanced registery where the cows have to perform as well as exist is rapidly changing this.

Every day more and more cows are being developed into great performers at the pail. The grade cows of the various breeds are showing great cows. These have not had a chance to win prize money. The Holstein Association now has an ammendment to its by-laws to be voted on this month, in effect that the association will offer money prizes for records of grade cows when made under the regulation that apply to registered cows.

[Concluded next week.]

A WOMAN FARMER.

The Press, Cleveland, O., says: "One of the greatest farmers in California is a woman. Twenty years ago, as Miss Minnie Eshelman, she went to 'Frisco and bought a big ranch, and although without previous experience, she made a success of farming from the very first year. She is now the wife of a physician, Dr. Sherman, and manages every department of her business. She has a large herd of Holstein cows, many of which have made the best records in the State. Last year the herd made a net profit of $500 a month. She has 250 acres in grapes and is a large winemaker. Her profits from this branch of the ranch last year was $13,000. Mrs. Sherman employs fifteen to twenty hands all the year round and, during the busy season, her force is often as high as fifty men. Mrs. Sherman is devoted to her husband and family, is a forceful writer and a great worker in all matters of charity and is greatly beloved by the people all over the State."

We think one or two statements above are not strictly correct. For instance, we think Mrs. Sherman, instead of being a "large winemaker" is a shipper of large quantities of table grapes.

However, it calls attention to the fact that a woman can assert her rights and do things and compel people—even some men—to sit up and take notice. As far away as Cleveland is, they have heard of Mrs. Sherman and her work. Cultivator readers hear of her and read of her work from her own pen each week.

The writer has been driven over her place by Mrs. Sherman and can say that much is to be learned by seeing her methods of work and how she accomplishes results.

Mrs. Sherman is one of those writers who gives good advice and at the same time maintains a place which is a credit to her neighborhood.

"Faith and works" go hand in hand on Minnewawa ranch.

CHARCOAL FOR SWINE.

Where hogs are kept in confinement it is noticed that they crave foods like charcoal, ashes, rotten wood, etc. It would seem as though such foods were of little value, for when analyzed they show but slight quantities of nutrition. Yet these foods are found to be excellent correctives for the hog's system, especially where large quantities of corn are fed.

The following method is advised by a noted hog breeder for making charcoal out of corn cobs. Dig a hole in the ground five feet deep, one foot in diameter at the bottom, and five feet at the top of the charcoal pit. Take the corn cobs that have been saved in a dry place and, starting a fire in the bottom of this pit, keep adding cobs so that the flame is gradually drawn to the top of the pit which will be thus filled with cobs. Then take a sheet-iron cover, similar to a pot lid in form, and over five feet in diameter, so as to amply cover the hole, and close up the burning mass sealing the edges of this lid in turn with earth. At the end of twelve hours you may uncover and take out a fine sample of corn cob charcoal.

It is a good plan to mix about eight pounds of salt to six bushels of cob charcoal, two quarts of air slack lime, and one bushel of wood ashes. Break up the charcoal so as the ingredients will become mixed thoroughly. The mixture should be placed where hogs may partake of it at their pleasure.

One of the hardest propositions with which sheepmen of the West have to contend with is making the long shipment from the mountain country to market, especially in the fall. At this season most of the consignments consist of lambs which are taken off green feed. They were put on the cars with the only chance of getting anything to eat at the regular feeding stations. They are given dry hay to which they are not accustomed and they do not take to it readily. It is bad enough when the railroads get the cars through on schedule time, which they rarely do, but when vexatious delays occur it is worse. The result is that lambs, though fat at the start, lose much of their plumpness before they reach market, but there seems to be no help for it.—The Ranch.

A drove of cattle crossing the bridge at Yuba City last week by some means were stampeded, when about the middle of the structure eight of them took a high dive into the river, 20 feet below.

Corn stalks are valuable fodder for sheep, and if cut green and properly cured, and then put through the shredder, there should be but little waste.

Keep a sharp lookout for anything wrong; find the cause and right it at once.

Give some oil meal with the grain ration. It is good for the digestion.

It is well to keep sheep in lots of fifty each.

Delays are dangerous with a flock.

One ram to fifty ewes.

The Ornamental Garden

YANG TAU.

AT THE last State Fruit Growers' Convention, held at Hanford last December, Prof. P. H. Dorsett exhibited various plants recently imported and now being tested at the United States Plant Introduction Garden at Chico. Some of these promise much of advantage in the short time which they have been observed.

Amongst these was the Yang Tau, a vine introduced from China. It is a beautiful vine and with that advantage bears a delicious fruit. It has not yet fruited in this country, but we now note in the Sacramento Union that the vine has this spring blossomed and now promises fruit for this season. Some of these plants have been distributed from the Chico station and two in a Los Angeles garden, show most beautiful foliage. The Union says:

There is joy at the National Plant Introduction Garden, located at Chico, and the superintendent and his associates feel sanguine that they will soon add another desirable fruiting plant to the number already growing in California. The cause of this elation is the recent development in the vines of the Yang Tau, a Chinese climbing vegetation sent to the garden two years ago, and which has since been watched with interest by the officials. The vines are now covered with two or three hundred flowers, and the expectations are that they will bear this year. The fruit is a sort of berry resembling a prune in size and shape and is highly prized in China.

As stated, the vines were first sent to Chico from China two years ago, along with some samples of the berry, which were placed in alcohol and are now at the garden. The first year good growth was made in the lath house in which they were planted. The second year the garden officials fully expected that blossoms would appear, and they were greatly disappointed when they did not occur. The present full bloom is therefore doubly satisfactory to the experts.

The growth in the two years has been such that the vines are now about an inch thick in the stalk at the base near the floor of the lath house, and a large portion of the roof of this place has been covered by the spreading, clinging shoots.

The flowers somewhat resemble an apple blossom, but are not constructed the same. They are pure white and about two inches across. The roof of the lath house is very striking, and it is said that even if the berry proves a failure in this country the vine with its flowers is ornamental enough to warrant its extensive planting. The flowers grow singly or in twos and threes.

There are two varieties of the Yang Tau at the garden, and both are covered with the blooms.

While the berry of the Yang Tau is most highly prized in China, it is not known what its value commercially will be in this country, but if prolific in bearing some use will undoubtedly be found for the fruit. In China it is preserved or easten fresh. Its size warrants much body to the single berries, and in time the Yang Tau may become one of our staple products.

A little elbow grease is worth a lot of oily phrases.

NASTURTIUMS.

The nasturtium is one of those annuals which should have a place in every garden no matter how large or how small. Anyone can grow them with perfect success, even a small child large enough to dig a hole and drop the seeds.

They possess every good quality which goes to make a perfect bedding plant, bearing intensely bright and beautiful flowers borne in the greatest profusion the whole season; not troubled by insects, thriving in poor soil and standing dry weather with impunity. There are few gardens where the beautiful nasturtiums do not prove one of the greatest successes and favorites for annual cultivation. If they were expensive luxuries, difficult to grow they would rival our choicest exotics. Their cultivation is simple as I have said, but I shall give a few points to insure success. An ordinary garden soil is best, not too rich, as then you would have more foliage than flowers; they will blossom profusely on poor soil, where scarcely anything else will thrive; still a happy medium is the best to strike. Loosen the soil well. Sow the seed in rows if tall, or masses if dwarf, and cover with fine soil the depth of one and one-half inches. Allow plenty of room, as the plants must not be crowded, if you desire them to become bushy and strong Do not allow the soil to become packed before the plants are out of the ground, but after budding commences do not stir the soil any more. Care must be taken to pick all faded flowers from the plants to have constant blooms until frost comes.

Sometimes nasturtiums are troubled with the cutworms, so if suspected they must be killed. The tall growing varieties should be planted for climbing over fences, rockeries, trellises, etc., while the dwarf kinds are the best for bedding, bordering, etc. I shall have a bed of gladiolusses this coming season with dwarf nasturitums for a border.—Deseret Farmer.

PLANT GROWS WITHOUT WATER OR EARTH.

Mrs. Wm. H. Grissim has a peculiar plant. It is called "Asia," and is a bulb which grows absolutely without water or earth. The bulb sits in an ornamented dish and from a small size has grown to a height of two feet. It has also put out a pretty blossom with a large leaf, the latter resembling the lily in form and shape. —Santa Rosa Republica.

VALUABLE REPORT.

The annual report of the California State Board of Trade, made at the annual meeting to the members of that organization, representing every section of California, gives some very interesting information concerning the resources and possibilities of the State, recent developments, and future requirements, in order to make the natural resources still more available, and incidentlly gives a summary of the work accomplished by the State Board since the last report was submitted.

The State Board has been able to pursue its work during the past year in spite of the diaster which befell San Francisco and which affected the entire State. The State Board had just completed its plans for renewed and greater efforts to meet the conditions which seemed to warrant the expectation of a more active movement of homeseekers and investors toward California than ever.

POTATO POINTERS.

THE writer is in receipt of a letter asking for certain information with reference to the conditions of seed and fertilizing matter in the production of maximum crops of potatoes. Touching upon the first point, the following experiments, conducted at a number of the American experiment stations, will be of interest:

First—An increase in seed within ordinary limits produced marked increase both in total yield and marketable yield.

Second—An increase in seed from one eye up to a half potato produced an increase in the net value of the crop. But the increased yield from the whole potato and from the half potato is not sufficient to cover the cost of the greater amount of seed.

The comparison of the half potato with two eye seed shows that:

First—For total yield (large and small) of ninety-five experiments, seventy-six are in favor of the half potato and nineteen in favor of two eyes.

Second—For marketable yield, that is a total yield less the small potatoes, of seventy-three experiments, fifty-eight are in favor of the half potato and fifteen in favor of the two eyes.

Third—For net marketable yield, that is, marketable yield less the amount of seed, of thirty experiments twenty-three are in favor of two eyes.

Fourth—For net value of the crop, that is, value of the crop less the value of the seed, of thirty experiments, twenty-two are in favor of the half potato and eight in favor of the two eyes.

The comparison of the whole potatoes with the half potatoes shows that:

First—For the total yield of fifty-four experiments, forty-six were in favor of the whole potato and eight in favor of the half potato.

Second—For the marketable potato, of forty-two experiments, thirty-six were in favor of the whole potato and eight in favor of the half potato.

Third—For the net marketable value above the seed, of thirteen experiments, seven are in favor of the whole potato and six in favor of the half potato.

Fourth—For the net value of the crop, that is value of marketable less the value of seed planting, of twelve experiments, seven are in favor of the whole potato and five in favor of the half potato.

Summary.

This is a summary of all the experiments conducted along this line by the American Experiment Stations up to and including 1893. I might also add another experiment made by the Utah Experiment Station which showed in a four-year experiment comparing small uncut potatoes with cuttings of equal weight to large potatoes that there was little difference in yield. The Wyoming Experiment Station determined that the total yield of potatoes from small, whole seed was greater than from cuttings, but the percentage of marketable potatoes was less. I think that we can summarize this matter by saying that the results of the station work have shown that good-sized whole potatoes have yielded much more of the total crop than cut seed and there has been nearly a uniform gradation in crop as to size of the seed passed from good-sized whole potatoes through small potatoes, halves, quarters, three eyes, two eyes, and one eye, but that with the whole potato, the marketable percentage of crop has been less than in the case of cut seed.

As to the second point, in large potato producing sections, where the supply of stable manure is limited, good results are obtained by the use of about 1500 pounds per acre of commercial fertilizers. Where the physical condition of the soil is poor, it it highly recommended to plow under a crop of clover, peas or other legumes and to apply 1200 to 1500 pounds per acre of a high-grade fertilizer, carrying all three of the elements essential for plant production, namely, phosphoric acid, potash and nitrogen. Even where the stable manure is used it is advisable to supplement it by the use of phosphoric acid and potash, inasmuch as stable manure is essentially a nitrogenous fertilizer and is lacking in the mineral elements mentioned above. In any case, an excess of either stable manure or fertilizers should be avoided, as it tends to produce an overgrowth of vines, thus excluding the air and sunlight and favoring conditions which invite attacks of potato blight.

A fertilizer which has given universal satisfaction is made up as follows:

Acid phosphate	600 lbs.
Nitrate of Soda	180 lbs.
Sulfate of potash	120 lbs.

On soils which are rich in organic matter the amount of nitrogen may be decreased and potash increased to 180 pounds with advantage. The first formula will correspond to 3 per cent. nitrogen, 8 per cent. of available phosphoric acid and 6 per cent. of potash, and should be used at the rate of from 1000 to 1500 pounds per acre. It goes without saying that to obtain the best crop the soil should be kept in physical condition conducive to the access of air and sunlight to render available all of the plant food possible.

GEORGE WRIGHT.

NO RULE FOR CUTTING SEED SPUDS.

L. D. Gale in an article in the Denver Field and Farm makes strong points in favor of cutting seed potatoes so as to give sufficient nourishment to the young, spouting plant. He says:

People who sell machines for planting potatoes well understand how farmers differ in their methods of cutting seed. The machine for cutting potatoes was really the outgrowth of a demand for seed-pieces of uniform shape and size to work in planters. Most of these machines slice or chop the potato into pieces. In some sections many farmers are greatly pleased with them and give them almost unqualified praise. Others are disappointed. The seed-pieces will not sprout and there are many misses in the field. The reason for this is quite easy to understand when we realize what a potato is and how its early growth is made. The eye or bud from which the little plant grows must be strong and vigorous and should have with it enough of the flesh of the tuber to support it until feeding roots are well formed.

Now if all varieties of potatoes were alike in shape and vigor, so that the eyes or buds were evenly distributed over the surface we might have a single rule for cutting seed and in most cases a machine would do fairly good work. We all know that tubers of varying types differ both in number and vigor of the eyes. Take, for example, a tuber of the Rural New-Yorker type. This is a round or chunky potato. The eyes are apparently well distributed, but when we sprout the tuber we find that only a few stronger buds at the seed end will sprout. The others are mostly blind eyes, which will make but feeble if any growth.

In a long and narrow potato, the buds are also well scattered and if we sprout a tuber, we will find good growths starting out all over it. The life of the tuber does not all go into a few strong buds at one end, but almost any eye is sure to make a plant. It is easy to see from this that there can be no fixed rule for cutting seed potatoes. In cutting the long, narrow type of potato of fair size, quarter it by cutting lengthwise and then slitting each long piece in the middle. Some growers would cut still finer by halving at least two of these quarters. We do not like such small seed pieces, especially for early potatoes. With potatoes of the Rural and Carman types it is better to cut through lengthwise and then each half in the same way.

Thus each seed piece carries at least one strong eye from the seed end. With smaller tubers we would cut once lengthwise and plant half the tuber. When a man undertakes to cut up a tuber of the Royal type in a machine, he will find that twenty-five or thirty per cent of the seed-pieces will fail. They are large enough, but the eyes are feeble, and if they start at all will make poor plants. Last year, a good deal of our seed was cut by new hands and we made a general rule for cutting lengthwise as with the round or chunky type of spuds, two or four pieces as the size of the tuber warranted. The trouble with long and slim potatoes when cut in this way is that the seed-pieces are so narrow that they break too easily. They give poor satisfaction when used in a planter, especially the crisp and dry varieties. Let the grower cut one or two different varieties and sprout them carefully and he will be surprised at the variation in the strength of the eyes.

SOIL FOR THE GARDEN.

The necessary requirements for growing good vegetables are proper soil, good seed, thorough cultivation, and careful attention. The soil for most vegetables should be of a sandy nature with a good sub-soil for drainage. A soil of this nature is especially adapted to such crops as spinach, lettuce, radishes, cucumbers, beets, celery, tomatoes, and early cabbages while a heavier soil with a clay sub-soil is best for such crops as onions, late cabbages, early celery and summer lettuce. The light, sandy soil can be cultivated much earlier than the heavier soils and will produce two or three crops each season while the heavy soil in most cases produces only one. Good stable manure has proved to be a complete manure, but if a second crop is to be grown on the same land an additional ton of some special fertilizer, suitable to that crop, is often necessary. But after all, the growing of all crops depends more on the man than on anything else.

Things that are almost right are altogether wrong.

315 South Main St. **Henry Albers Co.** Los Angeles, Cal.

Does this stream of water look good to you?

It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.

It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.

How many pump users can say this?

It shows conclusively that it pays to install good machinery.

We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it. Mail us a card asking for it today.

California Horticulturally

GRASSHOPPERS DESTRUCTIVE.

FRESNO reports grasshoppers as having appeared in destructive force again, and as threatening great damage to the vineyards and orchards in the vicinity where they have appeared. We have outbreaks of these pests every year in some portion or other of the State, but they rarely appear in destructive numbers two successive seasons in the same place. We shall always hear of them so long as the uncultivated foothills furnish them with breeding places, but as these breeding grounds become circumscribed, the swarms will lessen and their damage be reduced. Fortunately the destructive work of these swarms is even now confined to limited areas and is growing less. In the early history of California grasshoppers swarmed over the whole State but, as cultivation broke up their breeding grounds they have been driven back and back, until now they are confined largely to a few sections immediately aligning the foothills where the land is never disturbed by the plow, and they find a hard gravelly soil, with gentle slopes to the south or west, and here they still hold to the cost of the neighboring fields. The damage done by them is during their larger hopping stage, when they are partly grown and have exhausted the food supply of their hatching place; they then hop off into the adjoining fields and do great damage before their wings develop. When they acquire wings they soon fly off, and spreading over a wider area, their destructive work is apparently lessened.

LIGHT FRUIT CROP THIS YEAR.

Authentic reports now coming in indicate that there will be a shortage in the output of most of the deciduous fruits this season. Apricots especially, will be very short. The apricot is a very uncertain bearer and rarely gives a full crop oftener than once in three years, but is rarely a total failure two years in succession. Last season and this, however, have been almost failures, so far as this fruit is concerned. Cherries are now in the height of the season and are yielding fairly well, although not a full crop. Peaches are doing much better than they did last year, but still the crop will fall below normal. Pears are doing better, but the blight has reduced the output very greatly. On the whole, the outlook is for a better yield of fruit than we had last season but still for anything but a good crop.

RED SPIDER PREVALENT.

Very many complaints are being received concerning the increase in red spiders and the consequent damage done by this pest. Red spiders always appears in great force at the approach of warm, dry weather and at such time does its greatest damage. It is a pest, not alone of certain kinds of orchard trees, as almonds, (upon which it is terribly severe) prunes, orange, etc., but it is equally a pest on a great variety of greenhouse stock and is found on very many plants in the open, where conditions are favorable for its spread. The only remedy to be advised, and that not altogether a satisfactory one, is dry sulphur. This should be dusted over the affected plants; best if they are slightly moist so that the sulphur will adhere to the surface. The fumes arising from the sulphur, when it gets warm, have a destructive effect on the spider and will greatly reduce its numbers.

OLIVE OIL AND LONGEVITY.

Captain Diamond, of Berkeley, who claims to have attained the advanced age of one hundred and eleven, ascribes his unusual accumulation of years and good health to the continuous use of olive oil. He states that he has used olive oil in large quantities ever since he was twenty-four, and that with the proper use of olive oil one can be cured of almost any form of disease. One of the stock prescriptions of medical men for gall stones is a copious use of this article, and in the remarkable Berkeley man, who has lived so far beyond the common run of mankind, and claims that he will reach the two-hundred mark, the medicos have good support for their remedy, and olive oil should have a boom from both sources. There is little question, however, that there is no more healthful article of diet than olive oil, and proper diet is the best of medicine.

PEACH BLIGHT DECREASING.

It is gratifying to note that from later reports which are still coming in, that the peach blight, which was so prevelant and destructive last season, and from which so much was dreaded for this, is decreasing. It has made its appearance in a few locations, but not nearly in so virulent a form as last year. This was to have been expected, as this disease is of fungus origin, and dependent largely upon climatic conditions for its spread, and as these conditions are seldom two years alike, so this disease will rarely be destructive for any series of seasons.

PEST SEASON NEARLY OVER.

The season of abundant pests is now nearly ended, and while there still remain enough to worry the producer, still they have reached the climax and are now on the decline. The latter part of May is the worst portion of the year for insect pests. It is then that cutworms are doing their greatest damage, when grasshoppers are traveling forward into the orchards and fields and when all kinds of aphids appear in swarms on various forms of vegetation. As the hotter weather approaches the cutworms become moths, the grasshoppers acquire their wings and fly away and the plant lice are killed off to a great extent. Still we have all these pests in swarms long enough to do vast damage, and it is well to be prepared for them another season, bearing in mind the experience of this. Precautionary measures may be taken against all. Thorough cultivation, clean culture, the plowing up of their breeding grounds will do much to check the cutworms and grasshoppers, two of the worst of our pests, while the spray outfit should be in readiness for the aphids as soon as they appear in the spring. Thorough winter spraying with salt, sulphur and lime will do much to check them. Precautionary measures are too apt to be overlooked and we act like the Arkansas fiddler with his house, when it rains we can't fix it, and when it don't rain it don't need it.

With the Citrus Growers

CITRUS PESTS.

THE question of pests is one that confronts every orange grower that operates in any country that grows oranges. The pests that infest some countries are practically the death of the industry until some means are discovered which will eradicate them. These hang like a cloud over the heads of some growers. Were it a fact that the orange pests attacked oranges only, these dire enemies could easily be quarantined against. But some of the worst will thrive on almost any kind of a plant. For instance, the cottony cushion scale seems to like some of the wild shrubs that grow in the dry arroyos, as well as it does the orange. Were it not for the Vedalia, the orange industry would not be where it now is in California.

The Black scale is the most universal bad pest that the California orange grower has to contend with, but its habits are of such a nature that it is easily controlled when systematically handled. Had this insect wings it would not be so easily handled, but still it would not be as bad as some pests. It does not injure the interior of the fruit to any perceptible degree and the injury done to the exterior is soon eliminated by proper and timely action. Still this is our most expensive orange pest, when taken as a whole. It has, as far as established at the present time, no effective natural enemies in the chief orange growing sections, that will hold it in check sufficiently to allow the disuse of mechanical means of combating it. There are but two orange tree pests in California that are held in check by natural enemies to such an extent that they are of no concern to growers, and those are the cottony cushion scale and aphis. The great hopes of orange and other fruit growers are the introduction of parasites that will prey on the pests to their practical annihilation. These hopes may be vain hopes. We have had many failures to one success. In this line of thought we will refer to a recent interview with a special traveling correspondent of the largest daily newspaper in Melbourne, Australia. He is intimately familiar with agricultural and horticultural pursuits in Australia and says that once given a start in that country, pests of all kinds multiply and increase with amazing and startling rapidity. While there are one or two exceptions, it is generally conceded that in order to keep the various pests within bounds, it is necessary to keep "maneuvering away" by some mechanical means. It does not pay to depend on natural enemies.

He also remarked that should the Fruit Fly find its way into California, it would knock our fruit industries "sky-high." It is the most destructive pest known to the Australian fruit grower. You pick a peach or orange, thinking you will have a refreshing bite, but find you have bitten into or opened a wiggling mass of nasty worms. The Mexican orange worm is not to be compared with it. We are told that all efforts to combat it have failed utterly. It has no settled habits and propagates from one year's end to the other. When growers find their fruit infested with the worms, their only alternative is to burn the crop. Imagine what would become of our fruit industry in California should this pest gain a foothold here.

The White Fly has made orange growing unprofitable in certain parts of Florida. This travels by wing from place to place and is a sucker in the truest sense of the word. They will swarm over the orange and extract the juice of the fruit (not only of the rind) so that the fruit is worthless. One bad feature of the pest is, that it attacks various varieties of plants. This insect has been the dread of California orange growers, so much so that the southern counties have quarantined against all kinds of Florida plants. Word has come that this pest has at last gotten to the Pacific Coast and is found in one section of the northern citrus belt. Active steps have been taken to eradicate it, and it is hoped that those in charge of the work will be successful.

COVER CROPS FOR COMBATING GUM DISEASE.

The success which has attended the efforts of those who are combating gum disease of lemons by cleaning away the soil so as to expose the original buds and keeping the ground well worked and soft about the base of the trees seems to indicate that these are the primary methods of control to which disinfection of affected parts and even cutting away of gummed bark are secondary, though perhaps necessary. The growing of cover crops is a great aid to both of these operations aside from their value in the control of brown rot.

It is generally acknowledged that the gum disease appears most frequently on trees in low places washed by irrigation and rain waters, especially the latter, in such a way as to build up a desposit of soil about the trunks which covers the collars. This condition also prevails often on heavy soils where too much of the plowing is toward the trees and settles there baking hard and becoming permanent during the dry summer months. Again it often occurs where the trees are budded too low or are improperly planted, leaving the collar so low that it is covered at the first cultivation. A good stand of cover crop during the months in which rain occurs will entirely prevent washing and thus eliminate the first and most important source of this evil. The value of cover crops in keeping the soil open and porous is too well known to require discussion. For this purpose leguminous crops are of course preferable since their roots not only open the soil in such a way as to give a better circulation of air but also supply nitrogen, a much-needed element.

In securing results in the control of gum disease it is necessary to get a growth close to the trunks of the trees where many cover crops fail to grow owing to the shade of the foliage. Opinion differs as to what legume will grow best in these places. Some favor vetch and others burr clover. The evidence is quite contradictory and it seems that the two are about equal in this respect, and when carefully and thoroughly sown to the very base of the trees will give a good growth even on the heavier soils most addicted to gum disease. The vetch produces a more spreading-root system than clover and also gives a greater number of nodules on the lateral branches. It therefore appears to be rather more desirable for keeping the soil porous and for a better distribution of nitrogen nodules.

In removing this crop in the spring it is generally necessary to use a hoe or similar hand-tool to reach under the trees, and if this be kept sharp the vetch or clover can be cut a little below the ground line leaving the roots to rot and furnish mulch, at the same time aiding the cultivator in keeping the soil soft and porous.—B. J. Jones.

CITRUS FRUITS IN LOUISIANA.

From a recent report of the Louisiana Experiment Station we extract the following, giving their latest experience with citrus fruits:

We have continued our growth of citrus fruits, enlarging the number of varieties, which this year have suffered very markedly from an attack of scale insects and the White Fly.

The method of spraying for the extermination of the scale insect, which has proven efficinet in other sections, is here complicated with another problem, namely, the control of the small ant that has become so numerous in the vicinity of New Orleans. These ants carry the insects and replant them on trees after they have been sprayed, and thus vitiate the results of spraying. We are now making arrangements with the Crop Pest Commission to carry on in co-operation with them some investigation looking to the control of this pest under the new conditions. It is to be regretted that the funds of the station will not permit the employment of an entomologist to devote his time to the study of the ant, as this insect is proving a great annoyance to all housekeepers in the infected territory and will probably become a menace to our orange groves, and possibly to our sugar interests. Our hybrid oranges fruited to a large extent this year, though likewise suffering from insect attacks. The object of experimenting with these hybrids is to see if we cannot get an edible orange that will withstand our coldest weather here without protection.—Florida Agriculturist.

A live saint needs to wear no symbol.

Vacaville shipped ten cars of deciduous fruits, principally cherries, by express.

Gold Medal Citrus Trees

Are fully described in our treatise of Citrus Culture, which is a trifle the best thing of its kind ever published. Contains about 50,000 words and 100 illustrations telling about oranges and lemons from the seed bed to the bearing orchard. Price 25 cents. Remember we are the largest producers of Citrus Trees in the world and stand ready to serve you with the finest nursery stock that can be grown. Correspondence invited.

WHITE FLY NEXT WEEK.

On learning of the White Fly on the orange trees at Marysville, Prof. C. W. Woodworth of the State University, proceeded to that place on investigation bent. Closest examination has convinced him that California has a true case of Alyrodes citri or Florida White Fly.

Many photographs were taken and a complete report compiled which is now being published by the State University.

The professor on visiting this office has granted to the Cultivator the use of his negatives from which cuts will be made and used with an article in the Cultivator next week.

FARMERS FORMING UNIONS.

On the front page of the Cultivator this week is a striking illustration of the independent condition of the American farmer today. He is shown to be beseiged by Wall street gamblers who desire to purchase his products, that they may create a corner on the commodities of the world's market. To their appeal he turns a deaf ear and in quiet confidence assures the invaders of his agricultural realm that he is quite independent of their attacks. The illustration is interesting, for it represents a general existing condition throughout the country. The farmer is coming at last to realize that he and not the Wall street speculator, holds the key to the prosperity of the world in the domain of agriculture.

Heretofore the farmer worked and worried, and the speculator garnered the profit of his toil. Drouth and insect pests, the extortion of the trusts were all for the farmer. The speculator profited quite as well when conditions were adverse for the farmer as when they were prosperous. It made no difference to him. It made no difference to the trusts.

The farmer worked from daylight until dark one year and the next year, while his life lasted. At the end, he had little more than at the beginning. On his rare visits to town he had the pleasure of looking at the palaces, yachts, automobiles and private cars built by speculators and middlemen from the profits of corners made on the products of the farm. Up to within a half dozen years the farmer had nothing whatever to say about the price he was to receive for what he had to sell. But today he nas. He is understanding his importance more and more—thanks to such leaders as Secretary Wilson, and the organizers of the Grange. He is getting a better knowledge of his importance as an industrial factor in the commerce of the nation.

Under an enlightened system of co-operation he has begun to realize what he can do.

In the industrial world this co-operation is called a UNION. No matter under what name it goes it is simply co-operation for mutual protection against the Wall street gamblers.

We are glad to be able to tell our readers that the farmers have made up their minds to put this system into operation, and that they have gone to work intelligently.

There are two great organizations of farmers in the country, both based upon a determination to give to the man who takes life's necessities from the soil a fair return for his work.

To this end, the work has been already begun in the farmers' organizations. The Cultivator congratulates the farmers, and greets as public benefactors the moving spirits in the great farmers' organizations.

The farmers of the country are the backbone of the nation. They develop the nation's real wealth, which is the wealth of the soil. They are entitled to a full share of that wealth and of the national prosperity. By combination, by insisting on fair prices for their wheat and their other crops, and by refusing to sell the non-perishable products except for a fair price, they have already added tens of millions to the annual return from the farms. They will add tens and hundreds of millions more annually as their unions increase in power.

THE WALNUT INSTITUTE.

The institute held at Whittier last week, confined to the discussion of the walnut industry, was attended by a very large number of growers from many counties in Southern California. We doubt if a more interesting institute, or one productive of greater beneficial results, has ever been held in this State.

Every feature of the industry so far as it relates to irrigation, cultivation, grafting, blight, die back, together with discussion of disease preventatives, was thoroughly gone over by experts. Of course there was a diversity of opinion on every topic discussed, but one feature impressed us which the readers of the Cultivator will be glad to note, and that was that in Prof. Ralph E. Smith, Supt. of the Pathological laboratory, the State has secured a most valuable instructor.

It is our firm belief that under his instruction, California will ere long be relieved of many of the serious conditions which have heretofore confronted growers along various lines of fruit and nut culture.

A GREAT CONGRESS.

The National Irrigation Congress which convenes at Sacramento September 27 next promises to be a record-breaker, so far as strong delegates can make it so.

The President of the Congress, Governor George E. Chamberlain of Oregon, has written to the Governors of the sixteen western States and territories which come under the provisions of the National Reclamation Act inviting them to be present and especially urging the importance of the presence of the executives or all these States. Governors of other States have also been or will be invited to attend and several are expected to come long distances for the purpose of attending and participating in the Congress.

The management announces a magnificent list of handsome and valuable trophies, comprising no less than sixteen handsome gold and silver loving cups especially designed and manufactured for the occasion and offered for interstate competition by prominent men and business houses of California and other States.

WALNUT GROWERS' CONVENTION.

Continued from First Page

now in existence were discussed, and the fac brought out that several kinds of good quality and decided blight resistance were already in existence.

The French varieties and several local nut were discussed and specimens exhibited. It i very necessary to remember that productiveness quality and other features are fully as importan as blight resistance. In regard to the presen acreage the possibility of top grafting to bette kinds was taken up, and the results of experiments and observations cited which seemed t show much hope in this direction.

Grafting.

The latter subject was continued in the after noon by Messrs. McNees, of Whittier and Crane of Santa Paula, together with Geo. Weinshank of Whittier, who had much experience and suc cess in this work. The best results had been ob tained by grafting wood not over 3 inches i diameter, and entirely new tops had been put o large trees in 3 or 4 years. The possibilities i this direction were quite a revelation to most o the growers, who had come to believe that walnut tree could not be grafted.

Root Stock.

In a general discussion which followed on th most desirable root for grafting nursery trees considerable difference of opinion resulte among the nurserymen present, owing largely no doubt, to the uncertain parentage of many o the so-called native or black walnuts. While al agreed that the black walnut root is far superio to the English, the comparative qualities of the California and Eastern black were a subject of much difference of opinion. It was apparent however, that much of the stock in use consiste of hybrids between different species and where definite information was available it seemed tha a hybrid root between the two black species o between the black and English gave the best re suits.

Mr. Taylor, of the F. W. Braun Co., Los An geles, spoke briefly on some experiments con ducted by himself in the control of walnut bligh by spraying. The results were not at all en couraging and he believed that the most promis in overcoming the disease lay along the line o increasing the crop by fertilization and bette culture and in securing immune varieties.

A Blessing to the Industry.

Mr. C. C. Chapman, of Fullerton, made a strong and interesting talk on the stability and prosperity of the walnut business in spite of the presence of the blight. Mr. Chapman believed that the disease was actually a blessing to the industry, in forcing it to seek general improvement and organization. He advocated strict attention to the best methods of intensive culture heavy fertilization, especially with phosphates o which he would use 75 pounds per tree each year, heavy winter irrigation, pruning out al dead and weak wood and an early cover crop o vetch in winter. He had great confidence tha every obstacle would be overcome, as they ha in every other of our horticultural industries.

Finally, Brethern.

If any general conclusions on walnut culture may be drawn from the whole discussion of the convention, they are something as follows The best variety to plant is not well established and probably not the same for all sections, bu plant grafted trees of what seems from all the information procurable, to be the best available kind for the section. The greatest immediate advance in walnut culture will probably be in the demonstration and multiplication of varieties Graft on roots from California-grown seed, of large black walnut trees or hybrids. Plant the trees in orchard not less than 50 feet apart o 60 feet in squares with a centre tree to be taken out later. Grow crops between the rows very sparingly if at all, and never for more than a very few years. As the trees grow older fertiliz liberally and grow a cover crop each year. I blighted twigs appear, keep them cut out a long as this is feasible. On bearing trees irri gate heavily in winter, except on land containin much moisture, and more lightly in June an just before and just after the harvest. Fertiliz heavily with phosphates, (40 to 75 pounds pe tree) and some nitrogen; put in a crop of vetc as early as possible and plow it in early an deep. Use all the stable manure possible. Kee all dead and weak growth cut off, and the tree pruned up from the ground enough to work un der them conveniently.

Next Year.

The convention adjourned on Thursday after noon, after voting enthusiastically to hold a sim ilar meeting next year.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

The total rainfall at Highlands during the past year has been 25.01.

The bee men around Hemet report a very fine crop of honey this year.

Barley is being received at Imperial warehouses in large quantities these days.

The Escondido Times reports the trial of a milking machine, which was entirely successful.

El Centro reports quite a storm of wind with some rain. Some barley was slightly damaged.

Imperial realty sales are looking up since the assurance that the Colorado river can be controlled.

Mr. Ray Trussell of Escondido has purchased a fine Jersey bull from the Tribble Brother's herd at Elk Grove, Cal.

Three trainloads of cattle arrived within two days last week at Imperial for fattening on the pasture lands in that vicinity

Redlands has a large output of fine black sage honey, which has, however, been somewhat decreased by continual cloudy weather.

Riverside Artesia Water Co., has struck a fine flow in a new well which has been increased by the installing of a Pomona pump.

The vicinity of Mound near Ventura has a live farmers' club, which hopes to have Conductor Neff hold a farmers' institute in the near future.

John Muir, the naturalist, visited Riverside last week. In an interview he unqualifiedly endorsed the efforts to reforest the California watersheds.

The grain crop at Canejo is reported heavier than anticipated earlier, as the cool moist days have given better opportunity for the maturing of the crop.

The people of Corona are swinging into line with an annual cleanup. Dead weeds and unsightly things along the street being compelled to give way.

The directors elected at the annual meeting of the Celery Growers' Association, held at Smetzer last week, were: W. H. Bentley, J. T. Shaffer, W. H. Chilson and D. E. Ford

The bean crop of Ventura county is looking more and more promising. The lima crop will be equal to that of last year, while blackeye beans show a material increase in planting

The Oxnard Courier reports that beets in that section will be one of the heaviest crops ever. This is notwithstanding the fact that the worms got in their deadly work and reduced the acreage very materially.

Mr. Geo. A. Smith, the creameryman of Corcoran, purchased two carload of registered Jersey and grade Jersey cattle around Elk Grove recently. This was the finest lot of cattle that has ever been assembled at the Elk Grove strock yards.

The Colorado river, which caused much anxiety along the levees above Imperial, reached its high water mark, 27.9 feet, last week. It has now receded slightly, and fears of trouble are practically passed. The cold wave which passed over the East and North is given the credit.

HORTICULTURE.

Corona olives promise a big crop.

The peach crop at San Fernando will be a large one.

Japs have planted over 700 acres to strawberries near Monrovia.

One cantaloupe grower at Brawley has fifty acres of early cants.

Berkeley capitalists are purchasing orange land at Arlington Heights.

Shipment of cantaloupes in carload lots began at Brawley the first of this week.

San Dimas claims and has the largest lemon packing-house in the world.

Apricots are two weeks earlier than last year in Santa Ana, and are now being sent to market in large quantities.

Apricots are ripe a month earlier than any season yet at Hemet. Pickers are at work getting the fruit ready to can.

High Grove and West Riverside are scrapping over which locality shipped the first apricots. May 20th is claimed as the date.

The grape crops in Cucamonga and Etiwanda are reported exceptionally fine. There are about 16,000 acres of vineyards in these two sections.

Coachella Valley makes the claim that its oranges will be so early that they will be able to demand $7.00 per box, for early December market.

The closing of the orange season at Riverside finds the growers claiming that it has been the most profitable season ever given to them.

The material shortage in the fruit crop of Ventura county and lack in the hay crop, it is hoped, will be made up by the heavy bean and sugar beet crops.

The Santa Paula olive growers are enthusiastic over the new olive oil mill, which it is hoped will be established there. It will have a capitalization of $500,000.

Imperial has a cottonwood tree from a cutting planted a year ago last March, trunk of which is eight inches in diameter, and the tree twenty-three feet high.

Mrs. J. C. Graham of Paradise valley brought to San Diego market the first wagonload of ripe pears on June 7, that sold for 7½ cents per pound to the Julian Produce Co.

Professors Steubenrauch and Eustis of the Department of Agriculture, visited San Dimas packing-house last week in their work of investigating the decay of oranges and lemons.

Ripe apricots were selling at 8 cents per pound on market of San Diego on June 7 from the ranch of Henry Johnson of San Pasqual and the Graham orchard of Paradise valley.

The big Limoneira lemon ranch near Santa Paula has been enlarged by the acquiring of Olivelands ranch. which adds to that already magnificent property 2300 acreas of highly improved land.

The walnut growers of the State held an enthusiastic meeting at Whittier last week which was so beneficial that a unanimous resolution was made to hold another, one year from that date.

Northern California

AGRICULTURE.

Six to eight dollars per ton in the field is the price of hay near Yuba City.

Salinas claims the erection in the near future of a $250,000 cement plant.

The Fresno fair hangs in the balance, as the lease of the ground has expired.

Winters has an improvement club which insists on people cleaning the roadways.

Twenty-four cents per pound is being paid for wool at Yuba City and Marysville.

"The country where farming pays" is what the Sentinel dubs the Hanford section.

Twenty draft horses were purchased at Woodland last week for shipment to Dawson.

Sonoma County Pomona Grange was entertained by the Bennett Valley Grange last week.

Farmers are suffering from a dearth of laborers in Sutter county, $2.25 and board being offered.

Trustees in Levee District No. 9, in Sutter county are asking for bids for improving their levees.

Of twenty-eight homing pigeons released at Roseburg, Ore., two have arrived in their home in Visalia.

Bee men in the neighborhood of Hanford, say that they have the finest prospects for a big honey crop.

Turlock Journal says Turlock Irish potatoes will be an article of commerce for they are the "finest on earth."

Directors of Levee District No. 1, near Marysville, expect to raise the levees of that district before another season.

Corcoran is swelling with importance over the fact that a $1,000,000 beet sugar plant is promised in the near future.

The levees and the canals in Fresno county are patroled night and day for fear that spring floods may cause serious breaks.

Siskiyou county had some good old-fashioned thunder storms with a cloudburst last week. The rain continued all the afternoon.

Three refrigerator cars of butter and eggs was sent to Los Angeles from the neighborhood of Hanford this week. Hanford must be some on butter.

San Joaquin county claims to plant 7500 acres to beans this season, about 1700 less than last year. This is caused by the excessive floods on the Delta lands.

Farmers of Turlock held an interesting institute under the direction of Prof. Fowler last week. One of its most interesting features was an address by Prof. Bioletti.

The State Veterinarian, Chas. Keane, of Sacramento, visited Tulare last week. There is a movement in that section to have the quarantine from that county raised.

Wheatland, known as the great hop center, is making herself a reputation as the producer of fine stock. One ranch recently shipped five carloads of cattle from that point.

HORTICULTURE.

The smallest ever is the prediction for the apricot crop this year .

Sixty-five dollars per ton is being offered for blackberries at the Sebastapol cannery.

The canning season has opened in Fresno with the canners paying $60 per ton for 'cots.

The Sentinel reports peach mildew as appearing in small quantities in the peach orchards about Hanford.

"Cherries is cherries," at Sebastapol, the price which started at 4 cents is now ranging from 6 to 8½ cents.

The total rainfall at Alta, Tulare county, was 15.91, and it is about an inch greater than the preceding year.

Ex-Governor Pardee offers a silver cup for the best exhibit of fruit grown by irrigation at the coming National Irrigation Congress.

The San Jose Mercury says that the best remedy for the wild morning glory, which has been such a nuisance in many orchards, is Lippia repens.

Something over 30 cars of green deciduous fruit has been shipped from Sacramento. A heavy crop of grapes is the promise of Cordelia, near Vacaville.

The farmers near Yuba City in district No. 70, are planning a scheme of drainage by which some of their most fertile lands will be saved in years of heavy rainfall.

Sacramento reports great interest in the coming National Irrigation Congress. Both Texas and Arizona have sent word of big delegations coming from the southwest.

Tulare County Times reports the appearance again of the vine hopper. It reports that the Italian-Swiss Colony Company near Madera, lost $10,000 last year through this one pest.

The Sutter County Farmer says that cling peaches will command top-notch prices. The output of that section will be about 50 per cent. of last year. Growers are talking $50 to $70 per ton.

O. C. Brown having a 200-acre ranch near Hanford sold the products of the ranch with the agreement that all expenses and gathering and delivery be borne by the purchaser, for $15,750.

The prune growers of Santa Clara Valley have appointed a committee to secure information as to prune markets all over the world, and also as to how large, or how small rather, the crop will be this year.

The annual blossom day, which has become a regular institution at prune blossom time in the little town of Saratoga, was suspended on account of heavy rains, but nothing daunted the Saratoga people and they persisted in having a festival later, which was held last week.

The following are the officers elected at the last annual meeting of the Butte County Citrus Association; Glenn W. Millar, president; J. A. Lawrence, vice-president; D. C. McCallum, secretary; Judge Lott, James Fitzgerald, Glenn Millar, W. H. McNamee, J. A. Lawrence, W. Dial, A. Bartley.

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis Worlds Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Profit in the Poultry Yard

LATE HATCHED-CHICKS PROFITABLE.

MANY times we are asked if June chicks are profitable? Is it better to break up our yards in June or to bring out a few hatches? And can we raise them? Many seasons, and this one particularly, conditions in the early spring were not favorable to young chicks. While many have had splendid results and have all the chicks out that they can properly raise and attend to, many have not been so fortunate and have fallen far short of their expectations and must either hatch during the month of June or be satisfied with a "short crop."

While the late hatched chicks have many drawbacks they also have many advantages and our advise is to hatch chicks out all of this month. You may have to be more particular but you can raise them to a good advantage.

Some of the Advantages.

By this time of year every observing breeder will know his best layers, or if he has not had the time to give attention that he may know which are his best layers; it is pretty safe to say that the poor layers have been broody long before this and what eggs you get now are from your best layers. Again, it is almost certain you can tell from which hens the fertile eggs come. If you have had the good luck to hatch some early chicks you will by now have formed some opinion of them and to tell which pen, or if you use the trap nest, which hen is producing the most promising youngsters. Thus you may correct some serious defect that may have cropped out, which will give you the advantage of two matings. If you are a beginner you will have gained much knowledge as to the proper method of feeding and care.

Early Maturity.

In many of the breeds the pullets mature and begin to lay at about five and six months of age, so if you are a fancier and raise thoroughbred stock to show or sell for breeders, you have fine pullets just coming into laying by January. If raising simply for eggs then you will have eggs to sell when the prices are highest. So there are many advantages to be derived from the June chick or even those hatched the first of July.

Care and Feed.

It will be necessary to treat the June chicks differently from the earlier ones. It is really necessary to have some green feed and perhaps we may have to plant something specially for them. Lettuce, rape or rye are good and they have the young tender shoots so much relished and the grass will be too tough. Shade is also a necessity.

One of the best runs for late chicks we ever saw was Kaffir corn; it provides shade and as the corn matures it will be splendid feed and they will get much-needed exercise by scratching for bugs, etc. Millet is also good, both for shade and food, but we prefer the Kaffir or Egyptian corn.

Take special care of the food. I especially recommend dry chick food for this time of year, for if you feed a soft food and should put before them more than will be cleaned up it will soon sour, and is apt to cause trouble. Feed only purest food; we prefer to feed often and just what they will eat up clean, than to feed indiscriminately. Should you give a meat food take extra care to see that it is not sour or tainted.

Every Morning.

You must pay special attention to the drinking water. It is absolutely certain if we neglect the water and the vessels that contain it we are going to have trouble. Wash your drinking fountains every morning and fill them several times a day, always taking care that they are not compelled to drink water that has been standing in the sun. A good plan is to wash the fountain and let it sun all day before it is used again. This of course takes an extra supply of fountains but it will pay at this season of the year.

Lice and Mites.

Always remember that lice and mites thrive extra well when it is warm, and unless we look sharp they will get the start of us. Keep the coops and yards thoroughly clean. Spray the coops once a week getting the liquid well into the cracks and crevices as these are the harboring places for the pests.

If you use an incubator and brooder you will not have so much trouble with lice. If you use hens, we would dust the chicks as they are taken from the nest with a good insect powder, and grease the heads with a little lard or vaseline to kill the head lice.

While perhaps it is best to hatch early, yet is is far better to hatch late than to fall short on the season's work, and there are actually some advantages to be gained over the usual methods.

AROUND THE YARDS.

Don't raise lice, mites and chicks in the same house; you will make a failure of one or the other.

* * *

Never allow your birds to become scared as you never get best results unless your birds are contented.

* * *

As soon as the breeding yards are broken up sell the surplus males; never feed birds that are not needed.

* * *

Sow a small patch of rye for the late hatched chicks. It will renew the ground and do the little fellows a world of good.

* * *

The roosts should be given a good coat of kerosene every two weeks, and nothing must be neglected even for a single day.

* * *

Air-slacked lime is one of the best things to throw aroung the house and on the dropping boards as it absorbs and odors and gases.

* * *

Paint is a good vermin destroyer; it also adds greatly to the looks of the poultry houses and fences. Use it liberally as it serves a two-fold purpose.

* * *

If your chicks have bowel trouble look for lice as nine-tenths of trouble starts from lice or mites; they sap all the vitality and leave them in a condition to take any disease.

* * *

If your birds are just mongrels

get a trio of thoroughbreds, or a few sittings of eggs and start with a good pen next spring. Blood in poultry will tell just as quick as in horses, cattle or hogs.

* * *

Did you ever figure out the relative cost of 1000 pounds of poultry and 1000 pounds of beef, and the time it takes to produce each; also the market price on foot. There is a good place to make comparisons.

* * *

Mary's father was trying the experiment of raising chickens with an incubator in his barn. The neighbors were much interested in this experiment, and meeting Mary one of them asked, "Mary, have you any little chickens at your house yet?"

"No, but we're makin' some," replied the little maiden.—Ex.

* * *

A Correspondent of the Dakota Farmer writes: "I see a great deal in print about how long after mating hens with a male before eggs are fertile. On March 20th, I mated nine Rose Comb Brown Leghorn hens with a high scoring cockerel. On the 21st, 1 egg out of five was fertile; on the 22nd, 1 out of 5; on the 23d, 2 out of 6; on the 24th, 2 out of 5 and on the 25th, 5 out of 6 were fertile. The hens had not been previously mated. In February, I mated eleven Black Langshan hens and began to save the eggs for incubators two days afterwards. And in about ten days placed all I had received in one of my incubators and only one egg tested out as infertile."

REARING LITTLE CHICKS.

The rearing of little chicks is perhaps the most important part of the poultry business.

To buy a fine pen, trio or eggs for hatching at a fancy price and get the chicks out and started and then have them die off is most discouraging. To mate up your best birds and hatch out chicks that you expect to be your prize-winners and get them coming along in good shape, then go out some morning and find them standing around all humped up and well started to the bad, makes a person's heart go way down in his shoes and he or she feels as if they would like to sell out pretty cheap. Well, that is what a good many of us chicken people have gone through. I have been all along the line and hit as hard as the next one, but had the hen fever so bad that I would not be discouraged.

The Brooder.

After hatching the eggs from sturdy stock perhaps the most of importance is the brooder. A good brooder that will furnish the right amount of heat and plenty of fresh air is the first thing we want. Then comes the feed.

The Food.

Of course we all know that a newly hatched chick has food enough in its little body in the shape of the unabsorbed yolk to last it for 36 to 48 hours and it is better not to feed them too soon. I will give the system of feeding that I have been using this season with good results.

My System.

My first food for them is finely cracked wheat scattered on the floor just outside the hover; I also have a low cover, or pie tin filled with cracked wheat where they can get it at easily. After they have picked at the cracked wheat for about two hours I give them chick grit. I kown that most people give them the grit the first thing but I believe it is better for them not to fill up on grit first as they are apt to get too much. I feed the cracked wheat for two days in this way then I use a commercial chick food. I feed them from now on just what they will eat up clean every two or three hours, thrown into the litter on the floor of their little run.

About once a day after they are a week old I put a mixture of bran feed meal, cut oats and fine beef scrap. This I put in a low box and they go to it in a way that makes me think that they like it.

I keep fresh water, chick grit and charcoal before them all the time, also a head of lettuce for green food. As they grow older I make their run larger and keep litter for them to scratch in as they grow better and are happier when kept busy. After they leave the brooder they should have as much range as possible and plenty of shade also.

Keep their drinking water in the shade. I speak of this because it seems to me that some people will never learn to do it. I go around a good deal and see so many people that leave the water for their chicks right out in the blazing sun. Still they wonder why they lose their chicks. Poor management is often laid to hard luck.

Another thing I wish to speak of and that is the getting right out with our stock and studying it. If things are going wrong with one brood get in and think about it; study the location. The way the wind blows these cool nights. Look for lice and mites. It may be the lack of proper shade. The water may be in the sun and it may be that the chicks are crowded. Find out the cause of the trouble yourself and don't spend your time asking your neighbors, as they do not know the conditions, and the chances are they haven't the time to go to your place to look you over.

Out Around the chicks.

Get out among the chicks yourself and study the cause and you will learn why things are going wrong. Last Sunday I got out in the hot sun with my chicks and found out that they needed more shade and they got it and are better off. I never would have known it by sitting up on the porch in the shade smoking a cigar.

If I have extra good success with any certain brood of chicks I make a memorandum of the conditions and feed and try the same system with the rest of my chicks.

Last week an acquaintance of mine stopped me as I was passing and wanted to know what was the matter with his chicks. He said he was having hard luck with them. They had been doing well until within the last few days, now they were dying off very rapidly.

I had often thought as I passed his place what an ideal place for chickens. Plenty of range and shade, and I knew he had plenty of money to make nice houses and coops. I promised to go over the next Sunday and did so.

The first thing in the way of chickens was a newly-hatched brood in a slat run sitting right out in the hot sun instead of under a fruit tree where it ought to have been that hot day, and there were plenty of them too. There was about a half pint of

Until the Chicks are over half grown, feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seed, meat, etc., in just the right proportion to make a full rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and will make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keop it, and will not get it, send $3.35 for 100 pounds, freight prepaid by us to any point in California.

Manufactured by the

West Coast Stock Food Co.

Germain Seed Co., Los Angeles, Distributing Agents for Southern California

wet mash on a board which would be sour in a short time sitting there in the sun. We went on farther and all the water dishes were out in the open where the sun could get at it, warm it up and spoil it. At one place a bucket sat in the ground and the water was filthy as the ducks had been paddling in it and I saw some chicks about two months old drinking that water. I thought to myself that it was no wonder that his chicks were dying. I told him of a few changes to make and I saw him this morning and he said he was not losing any more chicks. Was this a case of hard luck or of mismanagement? I refer to this case, as it shows where a good deal of the "bad luck" with chicks is that we hear so much about.

The chicken business is like any other business. It has got to have the proper attention and management. It will not look out for itself as some people seem to think.

Don't forget to look after those lice and mites.—A. W. Huskins.

NEW BUILDING FOR POULTRY AT STATE FAIR.

By the opening of the coming State Fair the directors of the Association expect to have completed a new building for the display of poultry. The building is to be used exclusively for the poultry exhibit and will be properly ventilated. It will have in addition to a sky light, side lights which will give plenty of light to show poultry to its best advantage. The exhibit of poultry is being encouraged by the state and is hoped that the exhibit will be larger than heretofore and that it will be represented from all sections of the state. We would like to see judges selected from different parts of the state and thus encourage more of the breeders and fanciers to exhibit

Quite a good story is printed in The Youth's Companion of a hen that was discovered in a neighbor's parlor cackling over an egg that she had just laid on a sofa pillow. The next day the hen went to the house of another neighbor and laid on egg in the kitchen sink; and a day or two later, it visited the third house, and left an egg in an egg-cup on the fourth pantry shelf. The news-gatherer who tells of this hen says that her owner is planning to establish an egg route and send the hens around each morning to deliver the goods.

In Denmark there are 224,000 rural landowners. More than half have not more than one acre, 96,000 have less than four acres, and only 2000 have more. The small landowners mainly occupy themselves with the egg and fowl industry.

An unsuspected draft striking the fowls at night while on the perches is responsible for many a case of cold in the head and incipient roup. Stop up the cracks in the henhouse.

The drinking vessels will need more attention as the days get warmer. Keep them clean and filled with fresh water, and always in the shade.

Upon the first of the month spray and whitewash your houses, roosts and nests that no vermin may live.

"A pretty woman can easily make a fool of a man."

"A pretty woman does not need to; upon her appearance he will make a fool of himself."—Huston Post.

Bees and Their Care

FARMERS SHOULD KEEP BEES.

IN THIS era of diversification, the thought occurs to me: Why don't more farmers keep a few bees? I have asked the question of some of my friends, receiving the reply: Oh, I don't know anything about bees, or I would like to, but they sting so bad; or another will declare there is no money in bees, because his neighbor had some bees in boxes that he never gets any honey from. All this, and the numerous questions asked in these columns of your valued paper indicate that among the masses of the farmers there is little actual knowledge of the "busy little bee," the greatest living example of industry and economy.

There is no investment a farmer can make that will pay as high a rate of profit as a few colonies of good bees, say ten to forty stands, according to growth of flowering plants or trees near by, provided he will handle them intelligently. By this I mean use proper equipment in the way of interchangeable hives, supers, frames, bee escapes, queen and drone excluders, a bee veil and a smoker. With anything like the care taken of their horses, cows, pigs or even the dogs, the bees will yield an average of 100 pounds of honey per stand per year.

Great Profit.

This is 150 per cent profit, for it is all profit; the work is hardly worth counting, but do not misunderstand me; to get good results you must go at it right, get good bees, Italians or Carnolians preferred, on account of their gentleness. Use the standard Langstroth dove-tailed hive which is made by all bee supply manufacturers, and use interchangeable frames throughout. A bee escape should be used on each stand to prevent the escape of the bees in swarming time. Queen excluders should be used to keep the queen from going up into the supers and making brood comb where only honey comb is wanted. A bee escape board can be used by those who are afraid of the sting so the bees can be driven from the supers down to the brood chamber when one wants to take out honey.

A veil is a safe thing to don whenever one goes around the bees. No honey should ever be taken from the brood chamber, for this is the storehouse of the colony.

Much valuable information can be obtained from the catalogues of bee supply houses, as they tell all about their various kinds of apparatus, how to use and their merits. Before I went into the bee business I got all the catalogues I could, then I studied them at odd times till I got some idea what to do and what to get.

If the farmer has no time or inclination to read and learn things, let his wife, son or daughter do it for him. By all means wake up and pick up the couple of hundred dollars going to waste every year.

SHADE FOR BEES.

Shall we shade our bees and, if so, why? Some bee keepers do not shade their hives, others do. Why do they do so? Is it really necessary and they thereby secure any more honey? These are pertinent questions to which it is difficult to give definite answers, but we should gain all possible knowledge of the subject. The temperature of a colony of bees in summer, when the brood is being reared, is nearly 100 degrees. Until the temperature in the sun reaches this point, shade is no benefit; rather is it an injury, as it deprives the bees of the warmth of the sun at the time when it should be of some benefit. When the temperature in the sun goes above 100 degrees and begins to climb up to 110, 120, 130 and 140 degrees, then every effort on the part of the bees is exerted to lower instead of raise the temperature in the hive. Crowds of bees stand at the entrance of the hive and with their wings create strong ventilative currents of air. The color of the hive has a great bearing upon the necessity for shade. Black or dark colors absorb heat, while it is reflected or repelled by white. We have seen the combs melt down in an old weather-beaten hive that stood in the sun; but we never saw them melt in hives painted white or light color, even if standing in the sun. For the comfort of the apiarist it is well to have a few scattered trees in the apiary, but nave their branches trimmed to such a height as to be clear of the head of the operator. Perhaps the whole question of shade might be summed up somewhat as follows: If the apiary is located where the cool breezes can fan the heating sides of the hives, driving away the heat ere it accumulates, and a broad entrance is furnished to each white or light colored hive, we are persuaded that shade is not so very essential; but if the hives are dark in color, or the apiary is located where there is not free circulation of air, we feel sure that the shade is an absolute necessity to prevent the combs from melting down, if for nothing else.—S. W. Farm and Orchard.

For cool cooking, less work and least fuel-expense use a

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Mildew of Grapes.

Is sulphur a cure or only a preventative of mildew on grape vines? Is it the fumes of the sulphur that destroys the mildew? Is it necessary to put the sulphur all over the vines?—A. S.

Sulphur is the best remedy or preventative for mildew and that which is used entirely, we believe, in fruiting season in the vineyard districts. It was treated fully in Mr. Mill's article in deciduous fruit department in our issue of June 6th, page 588, and in it you will note that it is the fumes of the sulphur which destroys the mildew. It probably would not be necessary for the sulphur to reach all parts of the vines. If by "cure" you mean wiping out of the disease so it will not appear next year, then it is not a cure, though it may totally destroy the mildew at time of application.

Sterile Figs.

I have a fig tree, which bears profusely, early each year, but before ripening, fruit all falls off, never maturing any fruit. There is a fig tree of another variety near by which matures fruit all right. What is the matter, and the remedy?—A. R.

This query has been sent to Mr. Roeding at Fresno, who is one of the busiest men on the face of the earth, but we hope he will get time to give us an answer for our next issue. However, our guess would be that the fig in question, is in need of fertilization of its flower. It can be secured by planting capri fig, and securing a supply of Blastophaga. If the writer had given something of a history where his tree was secured, it might help in giving the answer. However, we wait Mr. Roeding's reply.

Apricot Disease Again.

What is the matter with my apricot trees? Age from three to sixteen years. Soil varies from gravely to heavy adobe; no difference as to soil or age noticed. A heavy cover crop was plowed under this spring. Trees came out all right and some set full crop when all at once the tops wilt and the tree dies. Have grown apricots for ten years, but this is new to me. What can be done to save trees?—J. C. D.

Your query was answered by Mr. Mills in the issue of June 6th, on page 603, in which he advises the use of bluestone water in weak solution as a possible help for the trouble; also he holds out the hope that the disease will soon cease to be a menace.

Trees on Overflowed Ground.

What kind of trees would be the best for ground that overflows part of the year?—Louis Ped.

We know of no fruit tree that will stand long periods of submergence. Some species are more hardy than others and will recover after being under water for some time, but such treatment is fatal to most. The pear is best for such conditions as our correspondent describes, but this is subject to blight. Apples perhaps come next and might do under such circumstances, but there is no fruit which will give satisfactory results on land which is under water, even a portion of the year. We should certainly advise other than orchard crops under such conditions.—J. I.

Government Land.

J. H. R. and the many others whose queries are still coming regarding the San Jacinto forest reserve lands in the Yuciape Valley, was answered in last week's issue, on page 206. Any further information desired may be had by addressing the U. S. Land office, Los Angeles.

Mange on Horses.

If the inquirer of a remedy for mange on horses refers to page 602 of last week's issue he will find a remedy given there.

UNIVERSITY WORK IN SOUTHERN CALIFORNIA.

According to regulation the Regents of the University of California have adopted a general plan for the conduct of investigations and experiments to be pursued during the coming fiscal year. The provisions for work in Southern California at the Whittier Pathological Laboratory and the Riverside Citrus Experiment Station may be of some interest to the reading public. First of all the new laboratory building upon the site donated by the citizens of Whittier will be completed and will be equipped with the apparatus and collections which have been successfully used in temporary quarters. Investigations of the walnut blight will be continued through laboratory study and field experiments; and observations will be carried on as to local adaptability and blight resistance of a collection of various plants in the grounds of the State School at Whittier. Experiments with the use of fertilizers on walnut trees will be conducted, arrangement for co-operation having been made with the Cudahy ranch near Los Angeles. The investigation of the brown rot of the lemon will be concluded, and the detailed report published giving the highly satisfactory results attained in the treatment of this disease on the ranch and in the packing house. Citrus fruit troubles will be investigated including "gum diseases," "puffy oranges." etc. The experts will make careful investigation of tomato diseases and other miscellaneous plant diseases. At the branch experiment station at Riverside the planting of citrus fruit collections will be completed; experiments will be conducted with the use of fertilizers and other cultural treatments upon an adjacent area of bearing orange trees secured in co-operation with indiviaual growers in the various localities; and for the first time, observations will be undertaken looking toward the determination of the relative value of different roots for citrus trees. Finally, there will be investigation of bearing orchards of oranges and lemons as to soil, cultural treatments, etc., to determine the relations of these conditions to success and profitability.

SOME FACTS ABOUT CORN.

It was the corn given them by the Indians which kept the English settlers on Massachusetts Bay alive during their first winter in the New World; and yet this kindness did not prevent the English, during the Pequot war, in 1636, from destroying 200 acres of corn harvested by the Indians on Block Island.

Corn is believed to have been introduced into the Philippines from South America in 1520 by Magellan and was carried thence to China.

The Kaffir corn introduced for trial in the arid region in the Southwest where it has succeeded remarkably well, makes excellent meal.

Scarcely any other grain has shown the adaptability of corn. A native of the warm, moist parts of South America, it has gradually fought its way into the colder and dryer regions, until there are few sections in which it cannot be profitably grown. Its adaptability is shown in the fact that in the far North the plant is low and spreading, but maturing its ears all the same.

Experiments continuing for three years at the Indiana Experiment Station with barnyard manure as a fertilizer for corn, showed that while three tons to the acre increased the yield 14.9 bushels per acre, six tons made an increase of but 16.2 per acre. Thus the addition of the second three tons of barnyard manure estimated as having a value of $2 per ton as a fertilizer, or $6 for the three tons, increased the yield only 1.3 bushels or about sixty-five cents in value.

Government reports show that 95,535,000 acres were planted in corn this year, an increase of 1,500,000 over last year's area. Estimating the yield at twenty-five bushels to the acre the total production would be 2,388,375,000 bushels which, at fifty cents per bushel, means a return of $1,194,187,500 for this one crop alone, or only a little less than the gross earnings of all the railroads in this country last year.—Farm Journal.

After all is said about book farming, there is no doubt but that the educated farmer makes a better living and makes it easier, than the uneducated one. The same principle applies to the farmer, that applies to any other calling. It is nonsense to say that the ignorant is more independent than the intelligent. The practical intelligent man is at an advantage everywhere. But the theorist, the visionary man, is a failure, no difference what his vocation may be. It is not intelligence, not education, that hurts, but it is the impracticable theory.

The man who has a big crop of peaches this year will make big money. Apples and pears must be high. Every effort should be made to keep our fruit clean and have it well developed and highly colored. Men in the east are inquiring about our high grade fruit and are trying to contract it at good prices but are not meeting with success. My advice is take good care of your fruit and wait.

The regular shipments of grapes from Imperial began last week. The growers are hoping to receive the equal of last year's returns, some smaller lots at that time bringing 7 cents per pound.

Irrigation and Forestry

RUNNING OUT IRRIGATION FURROWS.

ONE of the earliest methods employed by pioneers in irrigation was to start at the source of supply and plow a furrow following the proper line as best one could judge. This was the system adopted by David K. Wall in May, 1859, when he planted the first garden tract in Colorado. After plowing for some distance, water was left in the furrow and if it flowed to the lower end the furrow was continued. If not, the furrow was changed until water followed the plow to the end. If water runs through a furrow, it will flow with greater ease in a larger ditch located on the same line. This method is not recommended for inexperienced irrigators. It is best when running a grade line in locating laterals to use some simple leveling instrument if a surveyor is not employed. Probably the most common type of a simple, home-made leveling device is the triangle with plumb line.

Contour.

It is necessary that field laterals shall be built with embankments rather than cut below the surface so that water will flow out at any points along them where the banks are cut. For this reason the grade line must be closely followed, when no cuts will be needed to make the water flow through the lateral. The construction will depend somewhat on the slope of the land. If a lateral runs across a slope so steep that there is a noticeable difference in the height of the ground above and below the lateral the dirt should be thrown on the lower side. If the ground is nearly level, the dirt shoul be thrown on both sides.

An easy way of making a small lateral is to throw four furrows together with an ordinary plow, then with the same plow or with a single-shovel cultivator plow out the middle of the ridge, making the bottom of the ditch just a little lower than the original surface of the ground. This keeps the ditch well above the surrounding land, and the water can be taken out without trouble. After a lateral has been made in this way the banks should be strengthened with a shovel wherever the dirt has been thrown out unevenly by the plow.

Catch the Gophers.

Laterals need more or less constant attention when in use. If neglected breaks, leaks and blocking of the channel may occur and probably at a time when water is most needed. A heavy storm may cause the washing out of the lower bank in the lateral, especially on a hillside. Such a break must be speedily repaired. Unceasing annoyance and trouble in the operation of laterals is caused by gophers which burrow holes on hillside slopes and will burrow from the bed or side of a canal or lateral down through the lower bank, coming to the surface again perhaps ten or more feet below their starting point. When water is first turned into a canal in the spring the water finds its way through these holes.—Denver Field and Farm.

Colton claims a fine setting of oranges.

ENCOURAGES FORESTRY.

The seventh annual meeting of the Counties Committee of the Promotion Committee, which convened at Petaluma on June seventh, was the most representative meeting that has been held, showing the widest representation of any of the sessions which have taken place. Every county was represented through organizations, there being one hundred and nine delegates present from fifty-two organizations. This is a growth which shows the increasing interest that is being taken in these meetings as their results and value are becoming more widely recognized.

The subject of the meeting was Forestry and Irrigation in California, and the papers read before the assembly covered various phases of both problems, pointing out just what benefits would accrue to the different sections of the State by a broad policy for the conservation and reforestation of timber lands and the extension of irrigation systems.

Professor Samuel Fortier, of the Forestry and Irrigation Service; W. A. Beard, Ex. Gov. George C. Pardee, G. B. Lull, State Forester; F. E. Olmsted, Forest Inspector U. S. Department of Agriculture; Francis Cuttle and others spoke.

Riverside, Santa Cruz, Monterey, Merced and Fresno each put in a bid for the honor of holding the next meeting, and as Fresno had put in its claim a year before that city was finally chosen.

In the report of the committee on resolutions, which was unanimously adopted, the sentiments embodied in the papers read at the two sessions were crystallized and provision was made for the appointment of a committee on Forestry and Irrigation, a sub-committee of the counties' committee which will carry out the recommendations of the meeting and the various organizations which assisted in the entertainment of the delegates.

WHAT'S THE USE.

What's the use o' growin' up?
You can't paddle with your toes
In a puddle; you can't yell
When you're feelin' extra well.
Why, every feller knows
A grown-up can't let loose.
I don't want to be no older—
What's the use?

What's the use o' growin' up?
When I'm big I don't suppose
Explorin' would be right
In a neighbor's field at night—
I won't like to get my clo'es
All watermelon juice.
I don't want to be no older—
What's the use?

What's the use o' growin' up?
You couldn't ride the cow.
An' rabbits an' the pig
Don't like you cause you're big.
I'm comfortablest now.
P'r'aps I am a goose:
I don't want to be no older—
What's the use?

What's the use o' growin' up?
When yer growed, why, every day
You just have to be one thing.
I'm a pirate, er a king,
Er a cowboy—I can play
That I'm anything I choose.
I don't want to be no older—
What's the use?
—St. Nicholas.

The first peaches shipped from Florida to New York this year were shipped on May 6, and the first watermelons May 8.

CONGO ROOFING

Congo costs little and lasts long, it keeps out the dampness and never leaks. The man who notices how his different roofs wear and how they protect the roof boards—the man who remembers or keeps records of costs and service, buys Congo.

Congo is easy to lay. Nails and cement free. Every roll perfect.

Sample free on request.

IF.

If all the skies were sunshine,
Our faces would be fain
To feel once more upon them
The cooling splash of rain.
If all the world were music,
Our hearts would often long
For one sweet strain of silence,
To break the endless song.
If life were always merry,
Our souls would seek relief,
And rest from weary laughter
In the quiet arms of grief.
—Henry Vandyke.

THE HEART OF THE WORLD.

GRAY shadows were creeping over the sand dunes beyond Pacific Heights. Only here and there a lanceolate beam touched the hills, from the crimson ball going out to sea through the golden gate. There was a scent of lilies in the air, mingling with the more wonted perfume of February roses. The hum of the city sounded far away, and the song of a meadow lark could be heard from a treetop.

The door of the house stood open, revealing a broad hall. There was a suggestion, in the dim light, of waving ferns and the silvery gleam of a fountain, in the conservatory at one side. From the door jamb there swayed in the breeze long ends of soft, snowy ribbon, holding in place a cluster of white roses.

In the center of a stately apartement that opened upon the hall stood a tiny white casket on slender pillars. Two candles burned at its head. By a window a man sat, gazing, with unseeing eyes, into the creeping shadows of the trees. A woman lay in a crushed heap among the pillows of a divan. Neither had moved for a long time. The little form in the white casket had been their all. Now it lay scarcely stiller than they.

Suddenly the silence was broken by the sound of a woman's voice, high-pitched and clear.

"Willy! Willy! oh, Willy!" it cried, A friend within the house hastened to the door. Along a pathway through the shrubbery a handsomely dressed woman appeared. "Oh!" she exclaimed, advancing; "have you seen a little boy about four years old? My little boy is lost! Some one said they saw him come in here. I cannot find him; and I am afraid he has fallen somewhere in the sand dunes?"

"Have you notified the police?"

"Long ago. They are all on the lookout for him. But he may be buried in the sand. We have been searching for hours. Oh, I have lost two little ones through death, but I never felt as I do this moment!"

The mother's heart wailed forth behind the cultured woman's enforced composure.

The woman who had been lying among the cushions came through the hall to the door.

"What is it?" she asked.

The friend put her arm about her and would have drawn her back; but the stranger spoke.

"My little boy is lost," she said, excitedly. "He is only four years old. We are afraid he is among the sand dunes."

"Oh," cried the younger woman, "I am so sorry! Is there nothing we can do? Cannot we help you look for him? The poor little fellow! Think of him all alone in the dunes! How did it happen?" And she put her hand in the stranger's for sympathy.

The latter was full of her story of coming home from a round of calls to find the child missing and the other children seeking him. Even as she spoke, voices could be heard calling from the sand dunes, "Willy! Willy! oh, Willy!"

"I must go," cried the mother. "Oh, my heart is breaking! Willy! Willy! Where can he be?"

As she turned, a passing zeyphr blew the white ribbon on the doorpost straight out across her cheek. She started back, dismayed.

"Why," she cried, "you have a dead child in this house!"

"Yes," said the other mother; "my only child, a little boy, just four years old, died this morning."

Tears came into the stranger's eyes. "Oh," she cried, "do forgive me! I am so sorry! I did not know. Dear heart! to think I should have troubled you. I, too, have lost two children by death; but this is more terrible. My little boy! You see I do not know where he is."

"I know," the other said, calmly. You must let us do what we can for you. Oh, I am sure you will find him. Let me go with you. We will search together. Not to know where your baby is! Ah, what trouble there is in the world!"

She seized a wrap, and the two women went down the walk together. At the corner they were met by a boy of perhaps a dozen years.

"Some children say they met a little boy like yourn goin' down toward North Beach," he said.

They hurried down the hilly street.

"Have you seen anything of a little boy, about four years old, playing about here?" asked Willy's mother of a homeward-bound laborer. "My little boy is lost."

"Shure, mem, now, that's very bad, an' I'm sorry," the man said, halting; "mebbe he'd be at th' p'lice station?"

"No, I've telephoned all the stations. Some one thought they saw him down here. What shall I do?"

The face of the big, rough man worked sympathetically.

"I'll kape me eyes open ez I go along home, mem," he said; "an' mebby I'll see th' little feller. Tut, now! What if 'twore me own little Tim? He's just four years old, the rascal, an' 'twad kill 'z mother shure. Ah, but it's wearyin' an' comfortin' to th' heart, mem, the children bez."

The way grew more squalid as they kept on toward the beach. On a door-step a woman sat holding a little child, and looking anxiously down the street.

"Have you seen a little boy?" the older mother began, and again the sad little tale was told.

"No," said the other woman; "but I hope you'll find him, lady. I know how you feel. Me heart's sore over me own little Joey, here, and me man away looking for worruk. The baby is that sick! an' Jim, me other lad, he's gone for the medicine. I don't know what's keepin' him."

"Let me see the baby;" and the mother, whose little one lay dead at home, reached out her jeweled hands. The child was placed in her arms.

"Why, he is very ill indeed!" she exclaimed. The little one's face was livid. The baby's fingers were clutched over each tiny thumb, and the tiny body shivered convulsively.

Willy's mother eyed the little form knowingly. "The child should be put into a warm bath, at once," she said.

The three women entered the house and busied themselves over the sick baby. She whose child was lost found a battered kettle and put water to heat over the single-burner lamp. The other one undressed the little form, while the wee sufferer's mother stood wringing her hands in helpless pain.

They worked rapidly, tenderly; but it was nearly an hour before the terrible convulsions were over and the baby resting on the bed.

"God bless you, ladies!" the poorer woman cried, as she saw relief creeping over the drawn face; "you've saved my baby's life!"

"But oh, my own little boy!" and the other mother hastened to the door. "It is quite dark, and I do not know where he is."

"Sure, lady, the good God'll never let your baby be lost!" but the two strangers were gone.

"Oh, where will he sleep to-night?" murmured Willy's mother. "Your boy is safe with God, but where, where is mine?"

Up the street an older boy came tearing. "Mamma! Mamma!" he cried, while yet afar off; "a policeman's found Willy and taken him home!"

"Oh, thank God!" said she whose child was with the All-Father—"thank God!" but the other could not speak.

It was a triumphal progress back to the more aristocratic quarter.

"They've found yer bebby, ma'am," a street urchin cried, who was calling papers on the street corner. A Mexican tamale vender volunteered the same information in broken English, and in the next block a woman threw open a window and leaned forward.

"A policeman took your little boy home, madam!" she called, joyfully.

Nearer home a gleeful band of children met them.

"He's found—he's found!" and the chorus rang throughout the neighborhood.

The two mothers kissed tenderly and parted. As the younger one turned to enter her childless home her eyes were swimming with the first tears she had shed that day; but they were tears of thankfullness.

On the door-step of the other home a man stood, holding a child in his arms.

"We've got him," he called, quickly, as he bent to kiss his wife; and then his arms closed tightly around them both.

"Oh, Willy," he said, "how could you frighten us so? Why did you do it?"

The curly head was raised and the blue eyes opened in surprise.

"Why, papa," said the little voice, "Mary said they wuzzent any or'nges for dinner, an' I went to buy some!"
—Independent.

"If you value your sweet wife,
Tell her so!

"There was a time you thought it bliss,
To get the favor of one kiss;
A dozen now won't come amiss—
Tell her so!

"Never let her heart grow cold—
Richer beauties will unfold;
If she's worth her weight in gold—
Tell her so!"

FOR THE COOK.

A good and an inexpensive breakfast sweet is apricot marmalade made from canned apricots. Measure the fruit, and to each pint allow three-fourths of a pint of sugar. Cook over a slow fire, stirring once in a while until the marmalade is thick.

A Summer Dish.

A tomato aspic is a boon in hot weather. To make this, strain the liquor from stewed tomatoes, and put it over the fire with a sliced onion, a bay leaf, a stalk of celery and one of parsley, and cook for fifteen minutes. Add to one pint of this one full tablespoonful of gelatine which has been soaked in just enough cold water to soften it. Stir until dissolved, take from the fire, season and strain, and set aside to cool.

This is good to serve with cold meat or with vegetables of several sorts. A delicious dish may be made by pouring a little of this aspic into the bottom of a mold, arranging cold chicken or cooked sweetbreads upon it, pouring in more of the jelly, placing on this a layer of the whites of hard-boiled eggs cut in slices, with the whole yolks among them, and then filling up the mold with jelly. This should be very cold and firm before it is turned out. It may be made richer by serving mayonnaise dressing with it. This jelly is also good if set to form in small cups, turned out on lettuce leaves, and dressed with a mayonnaise or a French salad dressing. Or it may be made in a large mold, turned out on lettuce leaves, and garnished with radishes.—Woman's Home Companion.

Beef Croquettes.

Take cold roast or corned beef. Put it into a wooden bowl and chop it fine. Mix with it about twice the quantity of hot mashed potatoes well seasoned with butter and salt. Beat up and egg and work it into the potato and meat, then form the mixture into little cakes the size of fish balls. Flatten them a little, roll in flour or egg and cracker and crumbs, fry in butter and lard mixed, browning on both sides. Serve piping hot.

Baked Hamburg Steak.

One and one-half pounds raw chopped beef, two cups of stale bread softened with half a cup of hot milk and cooled; two eggs, small onion minced, teaspoon of salt, saltspoon of pepper and pinch of ginger. Mix well and shape into squares; place in baking pan with a tablespoon of tomato, small onion and butter the size of a walnut on top of meat. Bake one hour, basting frequently. The potatoes should be boiled fifteen minutes, then drained, pared and placed in pan with Hamburg stake to cook forty-five minutes, being turned and basted often. Medium-sized potatoes are best for this. Serve arranged around the meat.

Asparagus on Toast.

Cook the tops or tender portion of asparagus in slightly salted water to cover. Make a cream sauce and add the asparagus cut in short bits and spread on slices of toasted bread.

"Don't wait until the iron's hot,
But make it hot by muscle;
Don't wait for wealth your father's got,
Take off your coat and hustle."

REAL JOY.

I love to think of boyhood days when
I arose at four,
And fetched of water from the well
8000 pails or more,
And then I'd wake the harrow up and
pacify the plow.
I love to lie in bed and think I needn't
do it now.

I love to think of boyhood days when
I the porkers fed.
I used to fix their breakfast food ere
yet the sky was red.
I used to dry shampoo the horse and
manicure the cow.
I love to lie in bed and think I needn't
do it now.

HOMELY HINTS.

The skins of fruit should never be eaten, not because they are not palatable or digestible or are unhealthy, but on account of the danger arising from microbes in the skin.

The soiling caused by persons leaning their heads against a papered wall may be greatly lessened, if not obliterated, by laying a sheet of blotting paper upon the spot and passing over it a moderately warm flat-iron.

A kitchen convenience which is not present in every household is a pair of sharp scissors. Scissors are used to trim lampwicks—which is wrong—and to cut papers and string; but seldom for trimming bacon and ham rinds, skinning parts of fowls which need skinning, and trimming salads. These are proper uses for scissors, and the use of them saves much labor.

To renew cane chairs—If the seats have become limp and stretched, so that they sink in the center, they may be made as good as new, if none of the strips of cane are broken, by well washing them in hot water and then placing them in a current of air to dry. This causes the cane to tighten up, and when dry, the seat will be quite flat as when first woven.

To prepare and set things at hand for breakfast is very quickly done when the supper work is done up, and to put back chairs, pick up papers and scraps in the sitting room just before going to bed takes scarcely more than a minute, and makes it seem a much more comfortable place in the morning, besides allowing one to make his way through it without delay or mishap if called up hastily in the night. Mothers, by all means, teach your daughters this thrifty way of doing things over night. Such a habit, once formed, will not be easily broken, and will help them to begin every day of their lives more easily and cheerfully.

GEMS FROM ROOSEVELT.

From President Roosevelt's address to the graduating class of Michigan Agricultural College recently, we note:

"The greatest of crops is the crop of children."

"The bulk of the people should work with both head and hand."

"We must develop a system under which each citizen shall be trained as an economic unit."

"No growth of cities and no growth of work can make up for loss in number and character of farming population."

"We must have a higher plane of efficiency and reward with consequent increased growth of dignity for the wage worker."

"Progress cannot permanently consist in abandonment of physical labor but in the development of physical labor so that it shall represent the work of the trained mind in the trained body."

Jump on a Keen Kutter Fork—put any Keen Kutter hand farm tool to the severest test you can think of. You discover an elastic toughness which restores tines, blade or handle to original form and position without weakening the tool. *Toughness* is one of the good qualities of all

ONLY ONE FOR A DOSE

A party of Sunday-school picnickers from Petaluma sent messages back to their home friends by carrier pigeons.

The Maple Grove Creamery was started at Hanford last week.

The Produce Markets

Los Angeles Markets

LOS ANGELES, June 12.

Some fruits like apricots, cantaloupes and others approaching more nearly their regular season have shown a slight lowering of quotation, but in the main quotations are fully maintained and market is firm. Butter shows the most marked advance. It is now 12½ cents per roll higher than last year at this date. It is rumored that the amount of butter stored is also far short of last year.

Butter.

Butter now commands 57½, an increase of 2½ cents in the past week. From the buyers' standpoint it is said that the butter situation will become serious this year. In speaking of the probable price of butter during this summer and the early part of the coming winter the majority of dealers say they do not dare make predictions, but one or two of the leading butter men say they fear a butter famine during the latter part of the summer and early in the winter before the rains have increased the supply.

Dried Fruits.

The dried fruit market is on the rise. Apricots, if there were any futures, would command up somewhere above 20 cents. As it is canners are picking up what few there are in the country at prices that preclude any drying.

Honey

A short talk with J. B. Jacobs of the Simon Levi Co. developed the fact that while there will be a short yield of honey there will still be a fair output. It is thought the Eastern shipments will exceed those of last year.

The prices we give are those at which the jobber sells to the grocer in small lots. The producer should take from this one cent a pound commission and freight to Los Angeles, and there will remain the net returns to him.

Potatoes

The potato market is firm and with supplies on hand kept small by light receipts and will probably remain so. Rhubarb maintains a favorable demand and the figures of last week are held steadfast. Beans are improved a trifle for some grades and the Wax varieties meets with much better business than the ordinary grades. There are but few hot-house Cucumbers for sale as trading is mostly in the Marysville grades. Squash is a trifle better in request than during the few past days and at nominal rates.

Citrus Market

LOS ANGELES, June 11, 1907.

Oranges are still going forward at a rapid rate and holding up in quality and price. A very few navels yet remain in California, but that variety is practically cleaned up.

Of sweets, mikes, seeds, bloods and others there are possibly 500 cars. Then comes the clean up of Valencias with perhaps 2000 cars, which is about 25 per cent greater than last year.

Some Valencias are going out now but mostly on special orders.

Lemons are in the dump yet and will continue to be until that eastern cold weather lets up. Foreigns continue to come but largely a very inferior stock which, in the present condition of market, go begging.

Shipments.

Shipments of Citrus fruits to date are 22,508 cars, of which 2181 are lemons. To same date last season 22,299 of which 2576 were lemons.

NEW YORK, June 10.—The market is very strong and higher on navels. Forty-one carloads of oranges and one of lemons sold today. Weather cloudy and threatening.

THE WORK OF THINNING BEETS

As soon as sugar beets are up they should be blocked and thinned and any delay in performing this work is likely to reduce the tonnage. A machine has just been invented by some Denver men for facilitating the work, but it will not be on the market this season. Blocking consists in cutting out the beets so that they stand in little tufts six or eight inches apart. This is usually done with a hoe but the machine mentioned will be able to block several rows at the same time and cover twenty acres a day. The thinning should immediately follow the blocking and must be done for the most part by hand. It consists in removing all but one of the young beet plants from these little tufts and is the most tedious and the most expensive single operation connected with sugar beet growing.

Single Germ Seed.

The fact that nearly all the beet seed balls contain from two to seven seeds makes it impossible at present to avoid the thinning process. It is not probable that any implement can be devised that will satisfactorily remove the unnecessary seedlings without injuring the one that remains. The only solution for this problem seems to lie in the development of a plant that will produce only single germ seed balls, but this consummation is far off and we will have to get down on our marrow bones for a few generations longer. Next to thinning, weeding is usually the most expensive operation, since this also must, as a rule, be done by hand. The cost of this process, however, depends very largely upon the condition of the soil with respect to the presence or absence of weeds and weed seed before the beets are planted.

Suppress the Weeds.

In addition to hand weeding, hoeing and cultivating are important factors in the suppression of weeds. It is usually necessary to hoe the beets once or several times and the number of cultivations will depend upon the conditions of the soil and the weather. The object of hoeing and cultivating is two fold—the destruction of the weeds and the conservation of moisture. In visiting the various sugar beet sections one cannot fail to be impressed with the number and size of the weeds that are allowed to thrive in some places while other localities are almost entirely free from weeds of any sort.

In some sections weeds of various kinds line the roadway for miles, scattering their numberless seeds by all the methods with which nature has provided them. In most of the general farming operations weeds are not as costly as they are in sugar beet production; hence this subject has not received in all communities the attention it deserves. The sugar beet grower must realize that to suppress and control the weeds will greatly reduce the cost of raising the crops. This principle of agriculture, as well as many others, might profitably be taught in our country schools but it probably never will be.—Denver Field and Farm.

"REMEMBER THE ALAMO."

When the farmer sets his son at work on a job it isn't always sure to be done, especially if the boy is yet in his teens and a ball game is on, but the Alamo works all the time.

What's the Alamo? It's a gas-engine. An economical, smooth to run; easy to start; simple to handle; sturdy old standby which makes its owner feel good all over.

Look around and see some engines then "Remember the Alamo" and see it work. It's a beauty. It will work faithfully for you.

Its manufacturers speak more at length of its merits on page 610 of this issue.

Among the many new introductions in horticulture and agriculture by the farmers at Elk Grove, Sacramento co., is a half an acre of rice, twenty acres of pistachio nuts, and one farm is experimenting with ninety-eight varieties of strawberries.

Visalia began shipping its green fruit output this week.

The White Fly in California

The Life Habits and History of the New Florida Pest Which Will Mean Fearful Financial Loss to This State Unless Controlled Immediately

THE white fly has stirred up the fruit growers of the State as no other event in fruit growing lines has in years. Interest is great on all sides, especially so with the citrus growers. What will be done is asked on all sides and the feeling prevails that strong action must be taken at once. Some advise "immediate fumigation and spraying of every shrub and tree in Marysville." Others say, "Wait till winter when results will be better." Still others say, "Cut and burn every shrub and tree in Marysville rather than have this pest escape to the rest of the State to do its damage by millions of dollars; the State can well afford to pay to the citizens there any price for their trees than to suffer this calamity."

We believe strong and early action will be taken in a thorough clean up.

The White Fly
Greatly Enlarged

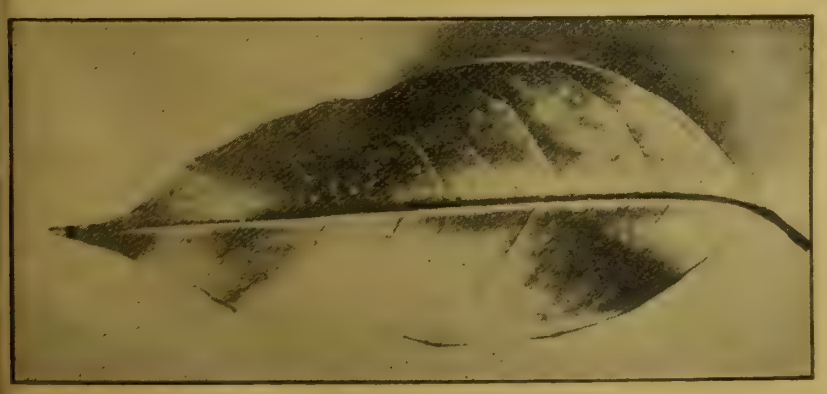
The StateUniversity is early in the field with information as to the gravity of the situation with Circular No. 30, "The White Fly in California," by C. W. Woodworth. The professor has been in the field working with the pest in Florida and now after thorough inspection at Marysville says there is no question whatever that it is the true Florida fly.

From this circular we quote:

A Serious Situation.

The white fly has at last become established in California. The most destructive insect in the citrus groves of Florida is this species of white fly, the Aleyrodes citri. It is considered by growers there as much more injurious than any of the scale insects attacking these fruits. Our trees were supposed to be free from the pest, but now a well established colony has made its appearance at Marysville at a center of travel by both steam and electric railways where the conditions seem particularly favorable to its spread over the State.

The seriousness of these facts to the citrus industry of this State



The White Fly on a Leaf. Natural Size.

renders it imperative that full publicity be given them in order that the proper steps may be taken to meet this emergency. We are not sure that the insect is confined to this one locality. Every one who has trees should carefully inspect them and submit all suspicious specimens to some one capable of accurately identifying them. The Experiment Station will be glad to examine and report on any that may be submitted for this purpose. It may be entirely possible to eradicate an insect before it has become widely established, but it will, if allowed to increase, become too widely distributed to effectively handle.

Our Climate No Protection.

Many have been very apprehensive of the danger of introducing this insect from Florida and have been instrumental in having most stringent laws enacted preventing the importation of anything from that State liable to be infested, while others have maintained that the insect could not live in this climate at all. In support of this idea it has been claimed that the insect must have been introduced into the State many times on nursery stock before these laws went into

Red Scale on Upper Side of Leaf
Which may be mistaken for the White Fly

effect and since that time on plants that escaped the attention of the inspectors. Many other species of white flies are able to live in California, however, including at least one injurious species. We do not have to speculate any longer on this matter since the insect in question is now not only existing here but thriving. Moreover, the insect is not appearing in the most humid parts of the State, but in the interior where the black scale is unable to thrive, that is, in a climate comparable to Riverside.

Though we now know that the white fly does live and thrive in our climate in the city of Marysville, there are those who still believe that our orchards are not menaced, still arguing on the basis of the climatic differences between California and Florida. The red scale, the black scale and the purple scale are all Florida insects and have not found our climate impossible. Possibly the white fly may prove to be different, but it does not seem the part of wisdom to permit the white fly to have free access to our citrus orchards on the chance that it may not thrive there.

Life History.

The white fly must have been in California at least a full year,

To Prevent Decay of Citrus Fruits

Instructive Preliminary Report of G. Harold Powell, in Charge of Field Investigations in Pomology in California for the Bureau of Plant Industry, Department of Agriculture

An investigation has been made of the decay in unbrushed and in brushed fruit free from visible mechanical injuries, in apparently sound fruit washed in clean water, in fruit washed in dirty water infected with blue-mold spores, and in fruit with each orange injured by the clippers, by a stem puncture or by some other type of visible abrasion. This fruit has been held packed two weeks in the packing-houses and has not been shipped. This line of work has extended over a period of three months and has been carried on in about thirty packing-houses in the principal parts of the citrus belt of Southern California. An average of the data gives the following general result:

Decay in Fruit in Packing-House Tests.

Sound fruit, unbrushed, showed 2.5 per cent. decay; sound fruit, brushed, 6.2 per cent.; sound fruit, washed in clean water, 4.0 per cent.; sound fruit, washed in dirty water, 17.8 per cent.; mechanically injured fruit, 37.4 per cent.;

Decay in Fruit of Different Regions.

A leading object of these experiments has been to determine the comparative susceptibility to decay of oranges grown in different parts of the citrus belt of Southern California. A comparison of the data obtained in the coast region with that in the upper San Bernardino valley region shows a slightly greater decay in the coast region..

The data, which Mr. Powell gives, indicate that the fruit which is handled the least develops the least decay. An orange with an unbroken skin in healthy condition and not overripe is practically immune to decay. The rot usually finds its way into the fruit through an abrasion or some other type of weakness in the skin. In commercial practice the fruit varies from sound to 50 per cent. or more injured when it is packed, the injuries resulting from clipper cuts, stem, gravel and insect punctures, scratches and other types of abrasion caused by carelessness in handling the fruit in the groves and in the packing-houses. Brushing the fruit probably increases the decay by inoculating injuries already present in the skin, or by actual injury when the brush is severe in type or is improperly regulated. Washing the fruit in clear water is not particularly injurious, but in commercial practice the water becomes infected with the spores of the decay which are carried into injured or weakened spots under conditions that are favorable to the vigorous development of rot. The greatest amount of decay develops in the mechanically injured oranges.

Investigation of Decay in Fruit During Shipment.

In the shipping investigations about two hundred shipments of fruit have been sent to New York under ventilation, icing and pre-cooling followed by standard icing, the fruit going forward at different lengths of time after packing.

Most of the shipments have included duplicate lots of apparently sound brushed or unbrushed fruit, sound washed, the regular commercially-packed fruit and oranges showing visible mechanical injury. The different lots have been packed from the bins from which the commercial lots are taken by careful sorting into the types mentioned. The decay has been determined on arrival in New York by the inspection of every orange included in the shipment. The general trend of the result of the shipments is brought out in the following summary of table:

Fruit picked in March and held three days before shipping, brushed, apparently sound fruit, showed 2.2 per cent. decay; washed, 3.7 per cent. decay; commercially-packed fruit, 4.9 per cent. decay; while mechanically injured fruit showed 15.0 per cent.

Fruit which was held five to seven days showed under same handling respectevely, 2.7 per cent., 5.1 per cent., 5.4 and 22.7 per cent. decay.

These shipments were made from sections in which the decay is usually severe, in cool, variable weather, much of the fruit leaving California at a temperature below 55 degrees Fahr. The least decay occurs in the sound brushed fruit, the commercial pack develops more, as it contains more or less injured fruit, and the greatest amount develops in the injured oranges. In another direction, the decay is proportional to the length of time elapsing between the packing and the shipping of the fruit.

Another table is given in which said cars shipped from a section in which the handling of fruit is comparatively sound in which the fruit was held three days before shipping and brushed, sound fruit showed 3.7 per cent. decay; washed fruit, sound, 3.8 per cent; commercially packed, apparently sound fruit,, 9 per cent; while mechanically injured fruit showed 18.1 per cent. decay. When the fruit was held five days the per centage of decay was nearly doubled.

But in contrast with that is another table of cars shipped from sections where the handling of fruit is carefully done and instead of 9 per cent. decay there is reported a 2.4 per cent. decay, while in the fruit delayed five days, instead of 11.7 per cent. decay, is four per cent.

The least decay is in the fruit handled with the greatest care and is greatest in the injured fruit. It is also proportional to the length of time elapsing between the picking and packing and the shipping of the fruit.

Decay in Fruit Shipped Under Pre-cooling.

In the pre-cooling group the fruit has been cooled to a temperature of 35 to 40 degrees Fahr. before shipment. The cars have been iced before loading and have generally gone forward under standard icing. Pre-cooling differs from ordinary icing in having the fruit reduced to a low temperature before shipment. The ice of the car then has only to maintain the refrigeration in transit. In regular icing, the ice of the car has to reduce the fruit to a low temperature and then maintain the temperature afterwards. The temperature of the fruit may not fall below 45 to 50 degrees in warm weather under ordinary icing in the entire transcontinental trip. Under these conditions decay occurs during the early part of the trip while the fruit is warm. The table gives the result of a group of shipments from sections in which the fruit generally decays badly and in which the handling of the fruit is roughly done.

Commercially packed fruit showed 2.3 per cent. decay on arrival when the pre-cooling was delayed one day; 6.2 per cent. decay when delayed three days and 9.1 per cent. decay when the cooling was delayed five days. Note, that was the commercial pack and on all three groups the average decay was 5.9 per cent. decay while, in the same cars carefully brushed, but sound fruit, showed only 2.9 per cent. decay.

The decay in the fruit under pre-cooling is less than in the fruit under ventilation or icing with the least loss in the sound fruit and the greatest in the fruit that is mechanically injured.

Beginning in April and extending to the present time another group of pre-cooled fruit has been shipped to New York with 549 to 584 boxes in each car, an increase of more than 40 per cent. over the standard car of 384 boxes.

The fruit has arrived in market in practically sound condition when cooled quickly after packing. The boxes are piled in the car 7 rows wide and 3 tiers high, the boxes on the upper tier being laid down. In the warmest weather the temperature of the fruit in the top tier has risen from 8 to 15 degrees, the middle tier from 6 to 10 degrees and the bottom tier from 4 to 8 degrees. Even with the rise in temperature the average temperature of the fruit on arrival is usually lower than it is in a car under standard icing, under the same conditions of weather in transit.

The Cold Storage of Oranges.

During the season large commercial quantities of oranges have been under observation in cold storage in California in order to determine the effect of the storage on the fruit and on its subsequent shipping quality. The fruit has been held from one to three weeks, then shipped in cars iced before loading, followed by standard icing. The fruit has arrived in market in practically sound condition when stored quickly after packing. In a general way it may be said that the orange may be held in sound condition for weeks or even months at a temperature of 32 degrees Fahr. if the fruit is sound and is stored quickly after packing. The fruit should not be held over three or four weeks, as the flavor of the fruit begins to deteriorate in a warehouse cooled in the usual commercial manner at the end of about one month. After a storage of from two to three weeks the flavor of the fruit on arrival in the market is equal to that of fruit shipped under ventilation or icing.

The Keeping of the Fruit on Arrival in Market.

An investigation is in progress to determine the keeping quality in the market of sound brushed and washed fruit, commercially packed, and mechanically injured fruit when shipped under ventilation, icing and pre-cooling. The investigation is not far enough advanced to discuss in detail, but the following general statements may be of interest. Oranges that are handled with care arrive in good condition under the different methods of shipment and appear to have good keeping quality when withdrawn from the car. Oranges that are mechanically injured may decay in transit when shipped under ventilation in warm weather, or may decay on arrival in market in warm weather. Icing the fruit retards the development of decay in

Deciduous Fruit Culture

SOME FAILURES.

IN EVERY section of the State are to be found orchards that during the early life of the trees, were thrifty and gave promise of being the beginning of profitable plantations. After they had reached the age of four or five years, just when they should be bringing in a good income, they dropped back and continued to be less profitable each year. No reason was discernable why the change should be, but in most cases the fault was to be found in the subsoil. Heavy clay subsoils are not as a rule detrimental to the growth of deciduous trees. In fact, they are much more preferable than gravelly soils that allow a very rapid drainage. A sandy surface with a clay subsoil is an ideal one for most deciduous fruit trees. But the reverse condition is not. Trees planted with the latter condition of soils will end in failure, for it is impossible for the mature tree to keep up a healthy growth with the roots in a stratum that will not hold the requisite amount of water.

On the other hand, the surface soil may be ideal, but at a depth of two or three feet a hardpan will exist that will turn the roots, hold the water during wet seasons and, taking all things into consideration, it is impossible for the trees to make a growth that will give a crop and in many cases the tree will die outright. At one time we had this experience with peach trees. Late rains came and before the water had drained from the soil, warm sunny weather came, the trees bloomed profusely and every indication was for a big crop of peaches.

These trees were six and eight inches in diameter at the base. About the time the leaf buds opened, a decidedly sweetish odor and of a sickening nature, was perceptible among the trees. Within a week, a large block of trees was black and dead. Investigation showed that a depth of two feet, a heavy hardpan existed and water would drain into holes at that depth when the trees should be in leaf. The soil had often remained equally as wet many times but not so late in the season. The drains might have saved the trees, but there is nothing sure about it as the rainy season extended into the blooming period. Trees near an open drain died in the same way.

These facts show the folly of planting fruit trees on soil with a hardpan subsoil. Land with a clay subsoil should be drained. Even if it is not, there is a constant movement of water through it that is not possible through soil underlaid with hardpan. The use of such soil should be entirely confined to growing shallow rooted crops or annual crops such as grain and hay. If the surface soil is good it may grow berries at a profit.

FIGS IN CALIFORNIA.

The old Spanish padres brought to California fig cuttings which produced the only variety that was grown in this State for many years, perhaps a generation. Like all other fruits which they introduced, it was one of the best.

There are all grades of fruit of every class, some poor under all conditions, some poor under some, and extra fine under other conditions; there are others that are of excellent quality under most all conditions. It is this last named quality that characterizes nearly, if not all, the old Mission fruits. These Spanish priests did not know what conditions they would encounter, so they selected the "middle of the road" kinds and disappointment did not meet them at many turns in their horticulural pursuits. The Mission fig is now one of the best grown in California. Aside form the Calimyrna fig, it is perhaps as profitable as any when a wide range of territory is considered. It does not sour as readily as many other kinds and brings on the market the same price as some better appearing sorts.

The growing of figs is in its infancy in California, for it is one of the best paying crops and its uses are being extended each year. Great quantities are used in cracker factories and while the Calimyrna fig is the finest grown, it is to expensive to be put to such use. The cheaper varieties must fill the order for general use and the Mission fig is a favorite. It will mature its fruit to a high degree of perfection over the largest known area in California of any variety known. It will not sour where some of the more prolific kinds do. The tree is a rapid grower and does not seem to have a limit in size, in fact will send its branches down to the ground, take root and form new trees like a banyan tdee. When trimmed, it will make a magnificent tree, rivaling many large oak in size. It is very resistent to drouth and will continue to make a rapid growth where the White Adriatic, for instance, will suffer.

THE TUSSOCK MOTH.

The office of Experiment Station at Washington in the last Station Record refers to California Station, Bulletin 183 by A. H. Volck, which treats of the California Tussock Moth.

Hemerocampa vestuta has been unusually injurious to apple trees in the Pajaro valley and elsewhere in California during the past few years, especially in 1905. The damage was most severe where the egg masses had not been picked off and destroyed during the previous year. In orchards where this precaution was taken the loss was 23.5 per cent., as compared with 65.6 per cent. in untreated orchards.

The pest in question lives on live oak, lupin, apple and cherry trees as well as other plants. There is one generation annually. The egg masses are laid near buds and the larvas burrow into the fleshy tissue or the fruit. The only parasites obtained by the author were tachina flies, but the eggs are attacked by a minute parasite.

Preliminary experiments showed that this insect is very resistant to arsenical poisons. The larvae live for several weeks after feeding on foliage sprayed with arsenate of lead at the rate of 3 to 6 lbs, per 50 gal. of water. On account of the heavy coating of hair the caterpillars are difficult to kill by contact insecticides. Whale-oil soap killed some of them, but kerosene was apparently harmless. The best methods of control seem to be picking off the egg masses as soon as the leaves fall in the autumn and the use of sticky bands about the trunks of infested trees.

SETTLED.

The Oregon Agriculturist makes a statement which will cause every walnut grower to sit up and take notice.

"A man in Southern California is confident that he has found an effective preventive of walnut blight. It remains for him to prove the fact by thorough tests. His method of applying the remedy is different from those in use as he gets his preventive or remedy onto the trees in the form of steam."

We believe that the advice given by Mr. Felix Gillet, to use the seedlings of French varieties of the Persian walnut as stock on which to graft is good for Northwest growers. The California Black is certainly to be used with great caution until we know more about recent developments. The American Black differs quite materially in habits of growth from the Persian walnut, and its availability is an unsolved problem. —Oregon Agriculturist.

The American Pomological Society will meet in 31st session at Jamestown Exposition grounds September 24-26. The preliminary announcement calls attention to the displays of fruits from northeast and southeast, the expected attendance of prominent men from abroad, the reduced rates by water and rail, and the special facilities offered by the exposition. Two sessions only will be held each day, so as to leave the evenings free. Papers and discussions will be centered on a few important topics. Wilder medal awards will be made for meritorious new fruits and regional collections.

A consignment of 1000 barrels of apples has arrived on board the steamer Celtic from Liverpool. The apples were grown in Australia, picked there in March and shipped to London. The shipping of this consignment is in the way of an experiment. At this time there is a scarcity of home-grown apples. The western crop has been used up. The apples are the best that Australia produces, hand-picked and each apple is wrapped in tissue paper to protect it during the voyage. From Australia to London the apples came as general cargo in the hold, but from Liverpool to New York the barrels were placed in the refrigerating compartments.

The standard remedy for the currant worm is white hellebore says Coleman's Rural World of St. Louis. This may be mixed with water at the rate of 1 ounce to 2 gallons of water and sprayed or sprinkled on the leaves or applied dry, either pure or mixed with flour. There is absolutely no danger in using white hellebore, for while it acts as an efficient poison to kill the currant worm, it may be freely used at any time, even on the ripening fruit without danger. After the fruit has formed it is unsafe to use Paris green. Careful watch must be kept for the worms.

This pest invariably starts in the middle of the bush and near the ground. Have the hellebore on hand, and when the first worms are discovered spray the whole bush, as a delay of a single day may mean the loss of all of the leaves and consequently most of the fruit. An ordinary whisk broom answers all purposes in spraying currant bushes with hellebore.

California Horticulturally

THE WHITE FLY.

ALL question as to the identity of the aleyrodes discovered at Marysville has now been removed and it is decided to be, without doubt, the destructive and dangerous White fly (Aleyrodes citri) of Florida. So far it has not been found outside of the city limits of Marysville and as Yuba is not a citrus growing county, commercially considered, there is yet hope that its ravages may be confined to a very small area, if it cannot be entirely extirpated. In Marysville there are a number of orange trees growing in the dooryards, but these are grown more for ornament than for any profit attached to them. Very many of these are large trees and among them are some of the oldest trees in the State. These are all badly infested, as is also very much of the shrubbery and other trees in the city which will harbor the white fly and upon which it feeds. Certainly Marysville has a very bad case of Aleyrodes citri, and stands in threatening position today in relation to the great citrus industry of the State. So long as this pest exists so near the great orange sections of California so long are they in grave danger, although it has not yet reached them. Adjoining Yuba county on the west, is Butte County, the great orange producing county of Northern California and all along the foothills, through the entire Sacramento and San Joaquin valleys, are scattering orange groves, which would greatly facilitate the spread of this pest should it once break out of its present confines and attack the commercial orchards. Vigorous action has been taken by our State Horticultural Commissioner, Hon. Ellwood Cooper, who, as soon as it was determined that the white fly existed in Marysville, made a personal visit to the infested section and has ordered the total destruction of all trees and other forms of vegetation upon which it finds lodgment within the city limits of Marysville. This is drastic, but when it is considered that the citrus industry of California, in which there are so many millions invested and upon which so much of our prosperity depends, is threatened it will be understood that noth which may hold out a hope of exterminating this pest must be stopped at.

There are whole sections in Florida in which it is impossible to grow oranges on account of this pest, and in others the industry is threatened with extinction by it. That this is no imaginary danger is evident from the following extracts from a Florida paper, the Florida Agriculturist:

The control or extermination of the white fly is a matter of paramount importance to the orange interests of the State. Those groves which have escaped infection until now are not immune. If this pest is not checked it is only a matter of time, and a very short time at that, before every grove in the State will be infected with this enemy of the orange. Therefore every grower of citrus fruit in the State should unite in well-directed efforts to destroy this enemy.

And the same paper takes the following from the Monticello "News:"

The white fly is here, and apparently to stay. They injure orange trees and privet hedges, and often appear in such swarms as to cause choking and sneezing when they envelop a citizen. They find very little citrus foliage here to feed on, and have taken the Pride of India, or China berry trees, where they luxuriate. Kerosene emulsion, or Paris green sprayed on the foliage which they frequent, will reduce their numbers.

The great distance intervening between the section in which it has appeared and the orange sections of Southern California, give the latter an added assurance of safety, provided proper precautions are taken, but if it is to be kept out, the vigilance of the Horticultural Commissioners will have to be redoubled and their hands should be strengthened in the work of protection by the supervisors and the fruit growers of every clean county.

UNTIMELY RAINS.

A rain in June in California is both unusual and unfortunate. At this time our fruit is well advanced, hay is down and in many sections grain is ready for the harvest. Such is the condition in Northern California, and at this time we have had a very heavy downpour. Cherries, which are hanging ripe on the trees awaiting the pickers, have suffered severely, and a very large per centage of the crop of late cherries will be ruined. Grapes have been seriously injured, and very much hay in the field has been seriously damaged if not totally ruined. Cherries were the one fruit crop which has turned out well this season. The greater part of the early varieties had been shipped, but there was still a very large crop on the trees, which usually is dependent upon by the canners. These have been severely damaged. A rain at this season is phenomenal and there has not been such a downpour as the present recorded since 1884.

ANNIHILATING MOSQUITOES

Several places in the northern counties, especially Stockton and San Mateo, have commenced a war of extermination against mosquitoes by destroying their breeding places. This is done either by draining, where the pools are shallow, or by coating the surface with crude oil, where they cannot be drained. There is no question as to the mosquito being a prime factor in the spread of many diseases, especially yellow fever and malaria, and it has been found that by curtailing the insects, both these diseases can be checked. From the standpoint of comfort it is worth much to get rid of these pests, and as a matter of health and the welfare of the community it is worth much more.

SISKIYOU TO HAVE A HORTICULTURAL COMMISSION.

The necessity of looking after the interests of the fruit growers is appealing to most of the counties, and several which have never before thought it of sufficient importance to look after them are now appointing Boards of Horticulture. Away-off Siskiyou is the last to fall in line and the supervisors of that county have now under consideration the appointment of such a board. The fruit growers realizing the importance of their industry and the fact that it was exposed to all outside dangers have moved in the matter and with apparent success.

"You never saw my hands as dirty as yours," said a mother to her little girl.

"No, but my grandmother did," was the reply.

On the Canadian Pacific irrigated tract in Southern Alberta water is obtained from the Bow River, which draws its supply from the main range of the Rocky Moutains. As the season advances the snow melts higher and higher up in the Rockies, and thus a constant, unfailing supply of water is furnished to the Bow which fills the irrigation ditches during the spring and summer season—at the very time moisture is needed to mature the crops.

Owing to the inexhaustible supply of water coming from the mountains, it is unnecessary to build storage dams or reservoirs. The flow of water in the Bow River has been measured year after year by the Government, and it has been found just what the minimum flow is. The Government does not authorize the building of irrigation works to take more than the minimum flow from the river, so the settler is assured that in the very dryest season he will have all the water he cares to use.

Every farmer knows that plenty of moisture on good ground, with a good climate, means a bountiful harvest. On the irrigated lands of the Canadian Pacific in Southern Alberta you will always have plenty of moisture. and as the ground is rich and the climate is the best, crops must be good.

Almost any kind of grain and root crops can be raised. There is a good market at the very door of the settler, and thus every opportunity for money making is to be found on this vast tract.

If you think of changing your location you will make a mistake if you do not investigate this opportunity. You will find nowhere else the chances for making money and the perfect farming conditions that prevail here.

Write us at once, and let us tell you how to take a trip through the finest agricultural country on the American continent, a the lowest possible cost, and how to obtain a home that will provide all the luxuries of life and make you and your children rich.

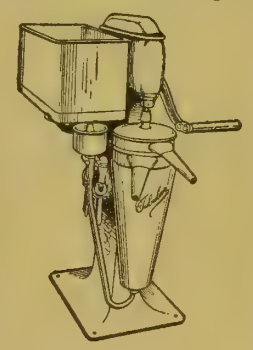
Because You Need The Money

It's **your** business and if you don't attend to it, who will? You cannot afford to keep cows for fun. That isn't business, and, furthermore, it isn't necessary. There is money in cow keeping if you go at it right, and besides there is more fun in going at it right than there is in staying wrong.



You need a **Tubular** Cream Separator because it will make money for you; because it saves labor; because it saves time; because it means all the difference between cow profits and cow losses.

Look into this matter; see what a **Tubular** will do for you and buy one **because you need it.**

How would you like our book "Business Dairying" and our catalog B. 260 both free. Write for them.

CALIFORNIA DAIRYING.

Continued from Last Week

THE old time dairyman with ordinary cows built his herd up by selecting calves of his best cows to raise, and bartered for the head of the herd from a neighbor. The poorer cows were used for beef and the best survived to produce calves to replenish the herd. This is a slow way to build up a herd of milking cows. Some men wiser than the rest took certain selected cows and by using only ten or twelve head and crossing their offspring, discarding the weakly ones and introducing new blood, in time formed the breeds of the world.

Within the breeds there are great families that stand out preeminent, these have been created by using the superior animals for mating and keeping on until the sires could be trusted to improve any herd. The power of transmitting good is, even then, greater in some of the offspring than in others. This trait is called prepotency. Examine the records of cattle offered at sales and you will note the great sires by the number of times the calves are said to be of such and such strains. In the horse family we say it is Wilkes, Electioneer or McKinney stock meaning there is a chance that the great prepotency of these bloods from noted sires may show out in the present colts.

Prepotency.

The Jersey as a breed are prepotent even down to the color, many cows only remotely Jersey wear the colors. The Jersey cattle from the Island have been bred in one line for two hundred years. During this period no new blood has been introduced as there is a rigid quarantine law that does not allow any cattle to be brought into the Island alive. The type is firmly fixed therefore and cannot be changed except to the detriment of her breed.

Environment.

The natural home of the Jersey cows on the moist wind swept Island where snow rarely falls, makes her the ideal cow for the coast dairies. She also does well on the town lots as she only requires a limited amount of grazing and requires little exercise. Vegetable growing for the London market is the pursuit of the people of Jersey rather than cattle raising or dairying. The cows receive a liberal amount of the unusable portions of the vegetables for her feed. Cattle raising with these people is an art and only a few cows are kept by each family, they are carefully looked after by the women and children. The result is a perfect type of the family cow.

On the California coast the Jersey cow meets with her natural home conditions of feed, I fear she sometimes suffers from the care of the loving hands of womenkind and becomes nervous and wild when in the hands of the man milker. The soft changing color of the breed suggests the sand dunes of the ocean.

The Gurnsey, another Channel Island breed is of larger frame, heavier and of brighter color. The Guernsey is a giver of rich milk of a high color, the butter made rarely requiring artificial coloring matter. The Jersey and her grade are the most numerous of the Channel Island breeds in the United States. The Guernsey, like the Brown Swiss, have not as yet become a favorite with dairymen as until quite recently they have become scarce and high priced.

The Brown Swiss cattle are famous producers in their own country, hardy and good size. Those brought to the Biltmore estate were fine individuals and as yet have only adorned a tale of what not to do, as it is an excellent example of the folly of bringing cattle of a mixed type into surroundings unsuited and unnatural for them. Here, side by side with the more plastic Jersey, they have proved to be unable to accommodate themselves to the change at once. No doubt after a few years they will show up as a breed to great advantage.

The Ayrshire in California is at present scarce. Many families seem to have suffered from the dual purpose idea. I have seen cows that looked like Guernsey among them, so pure was the dairy type. Some of these may be seen at Santa Barbara. Others are like the spiked horn red and white grade shorthorns, distinctly steery in type. The Scottish breeders seem to prefer this style, I am told that the Ayrshire breed in America is a more dairy-like type than those bred in Scotland. Until this breed is more fixed in type it is well to examine both the sire and the dam of any cows purchased for uniformity of type gives greater success.

The Holstein-Friesian and the Jersey are the most popular dairy breeds in California, these nick kindly on the common stock of the State. They also adapt themselves readily to change of feed and climate. The Holstein particularly distinguishes herself in consuming to advantage large amounts of feeds of low nutritive values which she turns into a quantity of milk of a medium per cent of butter fat. The alfalfa fields are particularly suited to her likings. The Jersey is at home on the rye grass pastures of the coast. The Holstein and Jersey are well fixed in the type and scrub cattle when mated with them at once improve and take on their colors and dairy form.

The Holstein cow belongs by inheritance to the flat valley lands. She cannot climb like a Jersey, nor can she be induced to seek the highest point of hills like the Ayrshire. She is lazy by nature and only asks to be allowed to stand in the alfalfa field all day and eat and then lie down in a shady place and chew her cud when she rises it is only to move to a nearby spot to eat some more. What is on the other side of the fence does not interest her if there is enough to eat on this side. Feed, feed and plenty of it is her requisite.

Jerseys and Guernseys are fair hill climbers, but the Ayrshire stands at the head. They climb like goats up and up the steep grades that it seems hardly possible that a cow could go, yet they go with ease.

The common cows of California all show the Shorthorn strains. In many cases by selection they have become smaller and of a distinct dairy type. These are excellent milkers and profitable cows. They are also good as a foundation for grade herds as the improved blood is kindly on this sort of scrub cows.

Today many of the common cows are being fed generously as the high prices of butter make it profitable to hold the cows in milking as long as possible. The building of silos is also going on, a little more slowly at present than in the past as the high prices of lumber is deterring many from building at once, but the idea is well received and the need admitted. The less progressive men are still feeding on the natural grasses and allowing the cows to go dry with the seasons, only running the dairy during the time of year when the prices are lowest for butter fat. These cows often have to hunt a living by browsing on bushes and eating the dried grass. This affords them merely a maintenance so that even when the fresh grasses come the cows have to first put themselves into condition before they can produce a profit. This sort of dairying is going rapidly to the wall, for always to have plenty when no man wishes to buy and not to have any when the market is keen is a poor way to make a living.

On the coast ranges many of the hills remain green from the fog and here the more progressive men have planted rye grasses and corn to feed the cows. The silo has not been extensively used in the coast part of the country but it is coming more and more into use. It is the cheapest way to extend the fresh grass conditions all the year round. A full silo means no drop in the milk when the grass goes dry. The use of soiling crops has not been extensively practiced as yet.

MILK STRAIN

P. O. Box 321 - Petaluma, Cal

The development along these lines promises to be rapid. We know at present that vetches, peas and oats and wheat are all valuable for winter feeding while Indian corn and sorghums come in for summer use. That it is profitable no one has ever tried the use of them to go back to the old way, but advances one step farther to silo as a still cheaper way of doing the same thing.

DAIRY CLEANLINESS.

I have been handling cows for twenty-five years and during that time have made some interesting observations. As a result of my experience, I have come to the conclusion that the making of good dairy products, either butter or cheese, is based very largely on one principle, namely, that of cleanliness.

If dairy cows are healthy and if they are fed good grain and fodder, as they are usually fed on the farms of the Central West, the milk from one cow will make practically as good butter as the milk from another. To go further, the milk from one herd may be manufactured into just as high class products as the milk from another. Why then is there so much difference between the produce turned out from the different private dairies and indeed from the different creameries?

Unless one will make up his mind to be clean in every operation involved in dairying, he had better go out of the business because he can never hope to make high-class and therefore high-priced produce.

Not long ago, I was visiting a fellow dairyman and was present at milking time. One of the cows planted her muddy feet squarely in the milk pail, in my presence, and pulled it out again without knocking it over. To my surprise and disgust the milking of that cow was continued in the same pail and the milk was then added to the general supply.

Now, imagine what kind of a batch of cream one would have after collecting it three or four days where scenes like that are enacted daily. It is absolutely impossible to make good butter when milk is handled by any person or persons who are so coarse in their instincts as to shut their eyes to a filthy act of that kind.

To me there is no satisfaction in the business of dairying at all unless I know that every one who handles the milk, cream or butter, takes every precaution to keep the product clean. When this is done, you can tell something about what the ultimate product will be. Good milk means good cream and good cream means good butter. The cream will ripen uniformly and butter will come after churning about the same length of time each week.

It is my opinion that the sale of dairy products could be increased at least one-half in our small towns and cities if the public could be educated to think that producers were cleanly in their habits. I find no difficulty in getting a premium of five cents per pound for butter the year around from those who have confidence in my methods.—Iowa Homestead.

One Ukiah hop seller disposed of 100 bales at seven cents, which is one-half cent advance over previously quoted prices.

COMMUNITY BREEDING.

Prof. W. A. Henry of Wisconsin, in a recent address, said:

"The next great advance will be community effort. The farmers in each community should meet at the schoolhouse and harmoniously agree upon one breed of dairy cattle for that community. If the most blood in the dairy herds now is Holstein, they should all agree upon Holsteins, and Holsteins only. If it is some other breed, then upon that breed. Where the farms are not large, instead of having one scrub bull on each farm, two, three, or even four neighbors should join and buy one or two registered bulls. The scrub bull has no place on hundred dollar land.

"Lake Mills, for instance, is a Holstein neighborhood. If every farmer within ten miles of Lake Mills will, from this time on, use nothing but registered Holstein bulls of high quality, the prosperity of this region will continue to advance. If he will use the Babcock test, and scales in addition, he will make still more money. It is urged that those farmers who are good breeders, and who already appreciate good blood in dairy cattle, embark cautiously but consistently in the breeding of pure-bred Holsteins. Half the farmers around Lake Mills should have no other than pure-bred Holsteins.

"Buyers always go where there are large quantities of goods for sale. No man likes to go a hundred miles with the bare hope of finding a cow or two at the end of his journey. The more he can see to select from, the more ready he is to part with his money. Already buyers come long distances to buy grade and pure-bred Holsteins at Lake Mills. If there were five times as many Holsteins there would be fifty times as many buyers. All honor to the breeders of Holsteins about Lake Mills! The early breeders deserve a vote of thanks from the farmers. Every farmer about Lake Mills has felt the benefit of these pioneers. The best way to show appreciation is to embark in the same enterprise and get some of the money that buyers are willing to pay out for good Holsteins. There is no danger of an over-supply of good Holstein cows, pure-breds or grades. If the market is going to be overrun, then the breeder of scrub cattle will suffer the most. If it is going to be hard to sell pure-breds and high-breds, it will be impossible to get any profit out of the scrubs."—H.—F. Register.

A householder at Corona was fined $7.00 for mutilating a fine large pepper tree in the way of his house-moving operations. The Corona judge must have a low ideal of the worth of pepper trees.

Santa Ana farmers are becoming interested in the growth of broom corn. The Bulletin says that one property owner offers seed and free use of land to those who will raise it one year.

The Santa Ana Register reports that after the ravages of the army worm were over the celery seed beds came out in fine shape, and the prospects of fine crops in large quantity is now good.

The Exeter Sun says that sweeter strawberries than Exeter's are unknown.

The Ornamental Garden

INTELLIGENCE IN FLOWERS.

MAURICE MAETERLINCK, philosopher, describes from a poetic point of view, the apparatus to be found in some kinds of flowers to prevent self-preservation and to secure pollen for the stigma from neighboring plants. The subject has been elaborately dealt with by Darwin from the point of view of the naturalist. In Harper's Magazine for February. Maeterlinck takes, among others, the common sage, a herb of which there are several species, to illustrate what he has to say about "The Intelligence of the Flowers." The important parts concerned in fertilization are the stamens, topped by anthers filled with pollen dust, and the pistil (topped by a stigma,) at the base of which the seeds are formed after the pollen grains have found their way thither. It has been noted that all showy flowers depend on insects for fertilization. Bright-colored petals blazon the fact that nectar within the flower awaits the visiting insect.

In the case of the sage, as Maeterlinck points out, the stigma is contained in the upper lip, which forms a sort of hood, in which are also the two stamens. To prevent these stamens fertilizing the stigma it is twice as tall as they so that they have no hope of reaching it. Moreover, in order to avoid any accident, the flower has made itself proterandrous, that is to say, the stamens ripen before the pistil, so that, when the pistil is fit to receive pollen the anthers of the stamens have already disappeared. It is necessary, therefore, that an external force should intervene to accomplish the union by bringing foreign pollen to the abandoned stigma. A certain number of flowers, the anemophilous flowers, leave this care to the wind. But the sage is entomophilous, that is to say, it loves insects, and relies upon their collaboration alone.

The insect depended on by the sage is the bee. "Observe the wonderful trap contrived by the sage—at the bottom of its tent of purple silk it distills a few drops of nectar; this is the bait. But, barring the access to the sugary field stand two parellel stalks, somewhat similar to the beams of a Dutch drawbridge. Right at the top of each stalk is a great sack, the anther, overflowing with pollen; at the bottom two smaller sacks serve as a counterpoise. When the bee enters the flower in order to reach the nectar she has to push the small sacks with her head. The two stalks, which turn on an axis, at once topple over, and the upper anthers descend and touch the sides of the insect, which they cover with fertilizing dust. No sooner has the bee departed than the springy pivots fly back and replace the mechanism in its first position; and all is ready to repeat the work at the next visit.

"This is only the first half of the play; the sequel is enacted in another scene. In a neighboring flower, whose stamens have just withered, there enters upon the stage the pistil that awaits the pollen. It issues slowly from the hood, lengthens out, stoops, curves down, becomes forked so as, in its turn, to bar the entrance to the tent. On its way to the nectar the head of the bee passes freely under the hanging fork, which, however, grazes her back and sides exactly at the spots touched by the stamens. The two-cleft stigma greedily absorbs the silvery dust, and the impregnation is accomplished. For the rest, it is easy, by introducing a straw or the end of a match; to set the apparatus going and to take stock of the striking and marvelous combination and precision of all its movements.

VARIATION IN PLANTS.

Plants differ one from another. No two plants are exactly alike. No two trees in the same orchard are alike. No two trees produce precisely the same grade of fruit, although they are the same variety. Life is a perpetual struggle either for man, beast, plant or tree. The strongest survive while the weak perish.

Yucca Whipplei
An addition to the foothill landscape all over Southern California at this season

The wide variation of plants and trees even of the same species is the struggle on the part of the individual to adapt itself to its surroundings. As no two plants or trees are alike it is not surprising that a wide variation is at times discovered which amounts to a new variety. An abundant or deficient supply of food may have helped to cause this variation. Climate may also have had its effect in causing the change in the variety. If located in the north the tendency is that it may become harder, and if located in the south its tendency is to become more tender.

Stock breeders have learned tha in order to keep a herd in the best possible condition, they must frequently introduce new blood. In stock breeding the results are definite and precise, but in plant breeding less certainty is possible.

To fully understand the art of crossing it is necessary to study carefully the botanical structure of the flower; select an unopened bud, open it and cut away the stamens before they discharge their pollen. Then cover the pistils with a paper sack and allow them to ripen or become receptive, that is ready to receive the pollen. This is evident by the swollen appearance of the stigma which also becomes covered with a mucilaginous substance. This will take from one to three days, depending on the weather. As soon as the stigma has become receptive, the pollen is collected from the variety it is desired to cross, and is applied to the stigma with a fine brush, great care being taken to prevent any other pollen from lodging on the pistils than that which is designed to use. To guard against this the pistils are carefully covered, from time to time the bud is opened and the stamens removed, until it has received its pollen from the variety it is desired to cross and until this pollen has entered the ovary fertilizing the ovules which swell and the fruit is set.

The subject of variation in plants is so large that it is impossible to give fully all the underlying principles in so short an article.—Exchange.

EVOLUTION.

Dedicated to Luther Burbank.

I was once a peach, just a common peach,
Burbank found me one day within his reach
And plucked me down, and looked me o'er,
And now you see I am a peach no more.
What am I? That's what I'd like to know
As I sit in this agricultural show.
I'm not a peach nor yet a plum nor 'cot
I sometimes think I'm just a common sot
Drunken with the wine of my own juice.
I give it up; there seems to be no use,
I'm what I am, not what I was before,
And yet I'm what I was and something more.
If you can solve the riddle let me know
And on your head my gratitude I'll bestow.

—G. P. Sullivan, La Crescenta.

Johnny's Luck.

Little Johnny saved his pennies,
Saved them for six months or so,
Saved to purchase cannon crackers—
Johnny's spirits now are low.
Someone stole his bank, his pennies,
Took his savings all away:
Don't cry, Johnny, you may, therefore,
Live to save, another day.

She (gushingly)—Don't you love all the fresh, green, young things?
He (judiciously)—Yes, if they ain't human.—Baltimore American.

The Vegetable Garden

LETTUCE FOR HOT WEATHER.

NO ONE should be satisfied with growing lettuce from early sowings. This appreciated salad vegetable should be sown at intervals of two weeks or so through the entire season, so that it may be cut when at its best. The most satisfactory kind for the hot summer weather is the crisp, heading type, and if planted in rich, loose soil and with frequent workings to keep the earth loose and mellow, and plenty of water is given it will make rapid growth and be sweet and tender. Good heads of cabbage, or butter, type may be had by a selection of the best varieties, and we would suggest the May King for a medium-sized early head, and the All New Seasons for a large, well-folded head to withstand the summer sun.

The crisp head type grows to a larger size, stands the heat well and heads quite firmly under good cultivation. It has thinner, crisper leaves than the cabbage type, blanching to a paper white instead of golden yellow. Of this type the Iceberg and Giant Glacier are the best varieties. New York or Wonderful grows to a much larger size, but the outer leaves are of a very dark green tint and less pleasing in flavor than the two preceding varieties. Any of these can be grown to please the most fastidious taste by giving shade during the hot, sunny portions of the day, and if tied up loosely the hearts and inner leaves are beautifully white. Many prefer the bunch, or cutting lettuce to the heading varieties as being more readily grown and as being available for use at any stage of growth. For June plantings of this type, the Black-seeded Simpson and the Morse are both good sorts with a large amount of leaves of a light golden tint, of handsome appearance and excellent flavor.

The cos, celery, or romaine type of lettuce may be had during the hot months with good cultivation, and is esteemed for its mild flavor and refreshing crispness. The best garden type is the Dwarf White Heart and its smaller, earlier prototype, the express cos. These do not need tying to blanch the inner leaves, as they fold over closely at the top.

The secret of summer lettuce is to make frequent plantings of small quantities of seed, and to keep the ground well stirred close up under the leaves every two or three days and supply moisture as the plants will soon run to seed if the soil is not well watered and cultivated.—Coleman's Rural World.

A SUCCESSION OF VEGETABLES.

There is scarcely anything that means so much enjoyment for the dwellers in country homes as a good garden, and to have this we must do more than simply make one planting in early spring says E. H. Riehl in Coleman's Rural World. It is a good plan to procure early in the season a goodly supply of the different seeds, especially such as may be planted at intervals, so as to have vegetables fresh and tender all the season through. Peas we cannot in this climate have after the hot, dry summer days come upon us, but by planting a number of varieties at different times in the spring we may have them much later than most people do. Sweet corn is one of our nicest vegetables and one that may be had from early summer until after frost under proper management. String beans are another important crop that will grow and do well no matter at what season they are planted after the ground is warm in spring. But they must be planted in time to mature before frost. Many people err in making but one planting of melons, for though watermelons and muskmelons should be planted for a succession the late crop is generally appreciated as much as the early one. Several plantings should be made of cucumbers also.

COST OF HAULING CROPS.

The information contained in Bullein 49 of U. S. Dept. Agriculture was secured from correspondents in 1894 counties in different States. The statistics deal particularly with 23 of the staple agricultural products grown in the United States and embrace the number of counties reporting, average miles to shipping, weight per load, cost per ton per mile, etc.

In a summary of these data the author of the bulletin says: "The average costs per 100 lbs. for hauling products from farms to shipping points vary in number of instances roughly with the relative values of the articles hauled, the more valuable product being hauled often at greater cost than the less valuable product. Corn, wheat, oats, hay and potatoes were hauled at costs ranging from 7 to 9 cts. per 100 lbs., cotton 16 cts. and wool 44 cts. per 100 lbs. Tobacco and hogs, however, cost only 10 cts. per 100 lbs. to be hauled from farms. The difference in cost of hauling between one product and another is largely due to the relative distance traversed and the relative size of load taken."

Statistics are also presented and discussed regarding the farmers' longest hauls and methods of hauling, with the effect of these factors on local and general prices. The quantity of farm produce hauled in 1905-6 is estimated at more than 49,000,000 tons and the cost of hauling at about $84,684,000 for the most important crops mentioned. The value of better roads, quicker methods of loading and unloading, and other factors are also discussed in their bearings on the reduction in the cost of hauling.

CHEAP HOME-MADE PAINTS.

Those who do not feel justified in using first-class paint on the cheaper sheds and outbuildings may find some of the cheap home-made paints satisfactory. Many farmers use mineral paints of various kinds. There are several kinds of paints in use in other countries where the conditions are more trying even than in America and which have the approval of their agricultural departments.

One is from the agricultural department of the Transvaal Colony in South Africa, as follows:

"Stir into one gallon of milk about three pounds Portland cement and add sufficient Venetian red powder or any other paint powder to impart a good color. The milk will hold the paint in suspension, but the cement, being very heavy, will sink to the bottom, so that it becomes necessary to keep the mixture well stirred with a paddle. This feature of the need of stirring is the only drawback on the paint, and as its efficiency depends upon administering a good coating of cement, it is not safe to leave its application to untrustworthy help. Six hours after painting this paint will be as immovable and unaffected by water as month-old oil paint. The party giving this recipe claims that he has heard of buildings twenty years old painted in this manner in which the wood was well preserved. The effect of such a coating seems to be to petrify the surface of the wood. Whole milk is better than buttermilk or skim milk as it contains more oil, and this is the constituent which sets the cement. If mixed with water instead of milk the wash rubs and soaks off readily. This cement-milk paint brushes on smoothly and easily—almost equal to genuine oil paint—is cheap and easily made."

The agricultural department of Queensland, Australia, has published several recipes for whitewash, viz.:

No. 1. Twenty pounds of lime (unslaked,) three pounds common salt, one-half pound alum. Slake the lime with boiling water until the consistency of the wash is similar to thin cream. To increase its antiseptic properties add one-halp a pint of crude carbolic to each bucketful of wash.

No. 2. To one-half a bucket of lime add two handfuls of common salt and two handfuls of tallow, or, better still, soft soap, at the rate of two pounds to thirty gallons of wash. Slake slowly, stirring all the time. This quantity will make two bucketfuls of wash which possesses the properties of being very adhesive and unaffected by rain.

No. 3. Slake lime with water and add sufficient skim milk to bring to the thickness of thin cream. To each gallon add one ounce of salt and two ounces brown sugar dissolved in water.

The germicidal values of Nos. 2 and 3 can be increased by the addition of one-fourth pound of chloride of lime to every thirty gallons of wash. Before applying the wash to wooden, metal, or stone structure, precautions should be adopted to clean the surface of foreign matter, thereby increasing the benefits of the solution. Care should also be taken to bring all crevices under the influences of the antiseptic.

Y. M. C. A. AGRICULTURAL CLUBS.

The educational department of the international committee of Young Men's Christian Associations has entered upon a campaign to encourage the associations in different parts of the country to start boys' agricultural clubs, and boys' gardens as means of employing profitably the time of the younger members when pleasant weather out of doors attracts them away from the association rooms. A leaflet has been published giving suggestions for organizing the clubs and conducting the gardens.

The Southern Pacific has issued a neat booklet with illustrations of San Francisco hotels, to show that the city is now prepared to entertain her guests nearly as well as ever.

A Cultivator field worker, looking over the Laguna and Empire ranches in the San Joaquin valley, reports fine crops of hay and grain, with the harvester in full swing.

Grain crops along the west side of the San Joaquin valley are reported in excellent condition. Late sown grain will not be as heavy as anticipated however.

DEVIL'S DUST THE VERMIN DESTROYER
Henry Albers Co. 315 So. Main St. Los Angeles

Does this stream of water look good to you?
It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.
It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.
How many pump users can say this?
It shows conclusively that it pays to install good machinery.
We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it.
Mail us a card asking for it today.

With the Citrus Growers

INSPECT ALL STOCK.

THE fact that we are in constant danger of having new orchard pests introduced makes it imperative that no plants of any description should be allowed to come into California (or the United States) from any foreign country where it is known that serious pests exist, except that they pass through a legally designated quarantine station that must be in charge of a competent man that has made the subject a study, not only in the laboratory but in the field. This latter qualification is a very necessary one, as it opens up to a man the numerous sidelights that do not develop in the laboratory.

The fact that fruit is being constantly imported into this country is a source of danger. In our last issue we referred to the fruit fly which infests apples and other kinds of fruit in Australia. It is a pest that not only renders the fruit worthless but repulsive. This last feature is a serious menace from the fact that it furnishes an incentive for those ignorant in things horticultural, to scatter the pest. Suppose for instance a box of apples imported from Australia, in which were a few apples infested with the maggots of the fruit fly, first from the box being sold on the street in San Francisco, to travelers going to take the train for Monterey. Suppose about this time the train reached Pajaro the traveler took a bite into the apple and opened up a mass of nasty worms. He would not put it in his grip or pocket, but out the window it would go. That would be a starter that would infest that section. Should the same thing happen on a Los Angeles train for Riverside, the orange growers would receive a solar plexus blow. It is all important that such chances be guarded against. Such pest are worse than anything now in existence in this country. We now have active men attending to this work, but they are powerless unless the transportation companies co-operate with them and when plants and fruit are transported through the mails, these chances of introducing these things becomes very great.

TRIFOLIATA STOCK.

Some years ago this new stock was introduced into Calfornia horticulture made easy by flattering reports from the South Atlantic coast. It was claimed that trees budded on it were much hardier than when budded on other stock and the trifoliata being of a deciduous nature; gave a slower flow of sap during the fall and winter months. It is claimed that this hardens the wood and is not so susceptible to freezes. This may be so in some cases, but it is not so in all. We had occasion to note the effect of frost on trees budded on trifoliata, sour stock, pomelo and sweet stock in the Pomona Valley. The trees were all planted the same season, side by side. The sour and trifoliata stocks were one year old and the others two years old when planted. At the end of the third year in the orchard the trees on pomelo and sweet stock were fully three times the size of those on sour and trifolata roots. After a heavy frost that curled the leaves on all orange trees in the district, there was no perceptible difference in the appearance of the trees except that the smaller trees seemed to be frosted the worst and had we not known what the different sets of trees were budded on, we would have decided at once that the difference in size was the only reason why the smaller ones were the worst frost bitten. We have no proof that such was not the case and therefore we allowed our decision to rest at that. When the trees are older a test of cold weather that is cold to the discomfort of the orange grower, it will be time enough to render a decision.

One thing is certain, and that is the size of the crop on the larger trees was much larger the third year than was the crop on the smaller trees—those on trifoliata and sour stock—when they were the same age. It will take more than two or three seasons to settle these questions and when they are settled to the satisfaction of the growers, one problem will be put behind them for all time.

There are two sets of experiments along this line being worked out at the Riverside Citrus Experiment Station; one taking in stiff, heavy clay running into hardpan and from there on to warm loam soil. Another set is growing on a decomposed granite soil that is typical of some of the best orange land in Southern California. There are Washington Navel and Valencia oranges and Eureka lemons included in these tests.

POWELL'S REPORT.

Continued from First Page

the unsound fruit to a greater or less extent and pre-cooling retards it still more, as the fruit is cooled more quickly than in an iced car. On arriving in the market the decay starts quickly in the fruit that is mechanically injured or is otherwise weakened, if the weather is warm, but the icing or the pre-cooling method does not appear to cause sound fruit to decay quickly when withdrawn from the car.

Refrigeration is No Guarantee Against Decay From Rough Handling.

The refrigeration-car service has made it possible to develop the citrus fruit business to its present proportions and to extend the trade to the most distant domestic and foreign markets. A refrigerator service, however, should not be looked upon as a means of overcoming the abuses to which the fruit may be subjected in the groves and packing-houses, but rather as an assurance against excessive loss after grower and the packer have performed their duties in preparing the fruit for proper shipment. To handle the fruit roughly in the groves and packing-houses, and then to depend on a refrigerator car service to land the fruit apparently sound in market is simply transferring the decay to the receiver. Carefully handled fruit is a valuable asset for the fruit shipper and an asset that the receiver and the consumer have a right to expect.

General Summary of Results.

There are a few fundamental factors that appear to govern the successful shipment of the orange. The groves should be kept free from scale and in good condition, in order to avoid the necessity of washing the fruit; the picking, the hauling and the packing-house operations should be of such a character as to preserve

the natural immunity of the orange rather than to make it susceptible to rot by rough mechanical handling. It is equally important to ship the fruit quickly after picking and packing at the lowest practical temperature. There has been an improvement in the methods of handling the orange in the last few years, but the amount of injury that occurs in handling the fruit in many groves and packing-houses is still excessive. Citrus fruits are probably handled better than any other large fruit crop in the United States. No other fruit crop is handled with such a degree of skill and economy, but at the same time it should be recognized that it is false economy to reduce the cost of the various handling operations to a point that makes a proper handling of the fruit impossible. To overcome the losses from decay in transit is a business matter related to the methods of organizing the citrus fruit business, to the systems of labor hiring, the methods of picking and hauling the fruit, the system of packing-house management, and the methods and efficiency of transportation. A system of organization, of labor handling or of packing-house management that makes the quantity rather than the quality and uniformity of the work the leading consideration is detrimental to the shipping quality of the fruit. It has been the aim of the Bureau of Plant Industry to point out the relation of the methods of citrus fruit handling to the losses that occur in transit and to suggest methods that help to preserve their splendid natural keeping qualities.

THE WHITE FLY.

Continued from First Cover Page

judging by its distribution and abundance at Marysville, but no observations have been made on its life history and habits except during the last few weeks since its discovery in the State. There is but little doubt, however, that it will prove to be much the same as in Florida. The most elaborate study of this insect is that reported in Bulletin 67 of the Florida Experiment Station by Professor H. A. Gossard. In the following account of the insect much will be taken from this publication:

The Egg.

At the present time the insect is chiefly in the egg stage. Nearly every leaf on the trees in this town were similiarly infested. These eggs are so small as to be scarcely visible to the eye singly, but the badly infested leaves appeared as though covered with mold. While rather less than half the town of Marysville is badly infested, still a careful examination would show the presence of a few eggs on nearly every tree.

It is not easy to distinguish between the eggs of the different species of white flies. According to Gossard, the egg requires from three to twenty days to hatch, according to the weather.

The Nymph.

The young insect on hatching very much resembles a young scale insect. Like the scale insects, the young white fly wanders over the twigs and leaves for a few hours, finally attaching itself by inserting its mouth-parts into the leaf. After thus locating itself the young insect soon secretes a wax in sufficient quantity to fill the space between the body and the leaf. Because of the small size and transparency of the body and this cementing of the body to the leaf the insect is almost invisible. In structure and habits the nymph is so like scale insects that if seen at all they could easily pass as young scales.

The full grown nymphs have a very much thicker skin than the younger stages and this remains attached to the leaf after the molt. On some tress at Marysville most of the old leaves are well spotted over on the under side of these exuviae.

The Adult Insect.

The name white fly was given to the insects of this class on account of the appearance of the adult insect. Its snowy white color makes the insect very conspicuous, notwithstanding its extremely small size. In the spring they appear in great numbers for two or three weeks and then suddenly disappear after laying their eggs, only a very few belated individuals coming out after the others. In mid-summer a second brood begins to appear. There is no distinct swarm as in the spring, but during the whole latter half of the year the adult white fly can be seen on the trees in greater or less abundance. After the colder weather of winter begins the adults almost entirely disappear and are not seen again until the spring emergence. The life of any individual fly is very brief, averaging, according to Gossard, between four days and a week. During this time the eggs are laid, and as many as seventy-five have been deposited by a single female.

The Detection of the White Fly.

At the present time the discovery of the presence of the white fly is of very great importance. After the insect has become so numerous that it is conspicuous either by its injuries or the swarms of the adult it is doubtful if eradication is possible, at least without very radical measures being employed. Much misapprehension can be avoided by getting a correct idea of the insect and of the things it is liable to be confounded with.

First it should be understood that the white fly is very minute. There is no other insect pest on citrus trees as small as the white fly, unless it be individuals of the red or yellow scale.

An insect much more likely to be confused with the white fly is the soft brown scale. This is a much larger insect than either the red scale or the white fly. One can very easily mistake, however, a very young soft brown scale for a partly or full grown nymph of the white fly. The soft brown scale is rarely as transparent as a white fly of the same size and is therefore much more easily seen.

There are many kinds of spots to be found on orange leaves which will be viewed with suspicion, all of which can be readily distinguished by the use of a good hand lens. The white fly exists on the tree only in four forms: the egg, the nymph, the old finally discarded skin of the full grown nymph called the exuvium, and the active flying stage of the adult insect. Any other kind of spot or structure on the leaf is certainly something else than the white fly.

Food Plants.

The white fly seems to prefer the leaves of orange and lemon, but will come to maturity on a variety of plants. This generally complicates the problem of their eradication or control. The following is a list of the plants upon which the insect breeds in Florida as recorded by Gossard: Citrus, all species; china berry tree, cape jessamine, Japan persimmon, California privet, golden privet, mock orange, Ficus, various species; water oak, prickly ash.

Character of Injury.

The injury done by the white fly is of exactly the same character as that done by scale insects, with the exception that being confined to the leaves there is no direct damage to the twigs and larger branches that makes the work of the San Jose scale, for instance, so fatal to the tree it attacks. Its direct effect on the foliage is similiar to that of the red or purple scale and its indirect effect like that of the black scale. Doubtless this latter will be considered the more serious since the excretions of this insect seem to cause the smut to cling with so much tenacity that it is practically impossible to remove it.

Methods of Control.

We have of course no experience in California in the control of this insect. The best Florida practice as recommended by Professor Gossard is as follows:

December—Spray with resin soap.
January—Spray with resin soap.
February—Spray again as above if necessary.
June—Spray with potash whale oil soap.
July—Spray with potash soap and sulfur.
August—Spray with potash soap and sulfur.
September—Spray with potash soap and sulfur.

Such a programme of spraying would seem rather hard to carry out to our growers, and possibly we might find that two or three fumigations a year would be as effective as the larger number of sprayings, or perhaps one fumigation followed by several summer sprayings. Our trees are mostly low and small compared with the Florida groves, so that fumigation is possibe as it would not be in that State.

None of the scale insects can fly, and therefore distribute themselves very slowly; but with the white fly in a community a clean orchard may become badly infested in a day, making summer treatment necessary no matter how thorough the winter work has been.

The Present Problem in California.

As far as is known the white fly

Concluded on Page 651

Oranges and Lemons

When the right varieties are properly grown and planted, are money makers. Our new booklet on Citrus Culture tells all about the standard sorts, planting, cultivation, irrigation and packing the crop. Over 100 illustrations and something like 50,000 words of text. The price is merely nominal, namely, 25 cents. May we have your name for a copy?

THE PRODUCE MARKETS.—Los Angeles Market; San Francisco Market; New York Citrus Market; California Citrus Shipments, 654-655.

THE WEED CUTTING LAW.

The Citrograph recently said: "In our opinion the bill passed at the recent session of the legislature of this state, providing that cities may clean vacant lots of weeds and that the expense of the work may become a lien upon the property for which it may be sold, will prove the unmixed blessing that its advocataes proclaimed. There are two sides to every question of this sort and enthusiasts for petty reform are not accustomed to looking at both sides. Clean streets and sidewalks in any city are surely most desirable, yet it is possiole to have them cost too much and, in this case, the effort to secure them may retard the growth of a city."

On the contrary we believe the law, had it been signed by the Governor, would have proven to be eminently satisfactory except to owners of vacant lots who do not desire to improve them. There are in every town owners of realty who buy lots on speculation. Many of these owners are non-residents who leave their property uncared for. Year after year, permitting weeds to grow thereon, never cultivating them. They be- birds to improved places and lawns and garcome a nuisance. Seeds are blown and carried by dens are made foul with them, costing the owners of these improved properties many dollars annually to get rid of them.

Why should non-resident owners of vacant lots be permitted to do this? Why should resident owners be allowed to leave their vacant lots in weeds to destroy the tidy appearance of the streets? Weeds are the evidence of shiftlessness. They mar the beauty of a town and they cause endless trouble to people along side of them who desire to keep clean grounds. The owners of these lots buy them for profit, and if they keep them clean they will find that the cost will be amply made up in the enhanced price they recive when they come to sell them.

The subject of noxious weed control was introduced into the County Horticultural Commission's law by the legislature of 1905 in an amendment placing the control of troublesome weeds upon the same basis as the control of insect pests. It is now lawful for the Horticultural Commission of a county to issue notice to property owners requiring the eradication of noxious weeds. If the notice is not respected the work may be done at the county's expense and made a lien upon the property and collected as a fumigation bill is collected. Just what constitutes a noxious weed might be an undetermined question in case of a contest, but the law if enforced would be of great assistance in cleaning up the weed nuisance.

TRADE CONDITIONS.

Both Dun and Bradstreet report a very satisfactory outlook for California products. Dun says this will be a most prosperous summer. Grain crops are in every way satisfactory with unusually large yield. Summer crops have matured finely with better yield than expected. owing to the wet spring. The bean crop will be as large as that of last year in most sections of the State. The beet crop will also make a fairly good return. The fruit grower is in luck this season. While the apricot yield will be light, peach, plum, berry and grape crops will be more than normal. Prospects are good for a heavy walnut crop this year, and olives are also heavy. More than 3500 tons are anticipated, and the best grade it is expected will bring $70 per ton. The winter vegetables have been very satisfactory. Over 6000 tons of cabbage have been shipped, realizing in the neighborhood of $122,000 to the grower. The cantaloupe crop also presents a very flattering outlook, 1100 carloads are expected to be shipped. The honey crop will also be a full crop and the price will be strong for the demand is good. Canned goods will reach the record-breaking price this season owing to failure in several Eastern States caused by bad weather conditions. California canned goods will sell for the highest figure in recent years. There is not a heavy demand for cured fruits, but still the outlook is quite satisfactory. The navel orange season is practically over, and it has been one of the most satisfactory so far in recent years. The call for Valencias is very earnest, and it is expected will be successfully settled, consequently the price will be strong. Lemons will improve from now on for the season is just opening when they will be in greatest demand. Taken as a whole, the Northern California grain and deciduous fruit producer and the Southern California orange grower will have every reason to remember the season of 1907 as among the best in his experience.

NOTICE TO CLEAN UP.

Horticultural Commissioner Cooper, has sent notice to all county commissioners to be watchful, and vigilant in the watch, for the White fly. From the notice we quote:

Notice is hereby given to the various County Boards of Horticulture that they take all necessary measures to prevent the spread of this pest, and, also, that they take all necessary means to eradicate it in those districts in which it has appeared, and to prevent its introduction in those counties where it does not exist.

There is as yet no known remedy for this pest which can safely be relied upon in the form of spray or fumigation, and

It is therefore ordered, That all infested trees, plants, or other forms of vegetation upon which the said Aleyrodes citri feeds shall be immediately destroyed, by the removal and burning of all portions liable to infestation. In the case of trees, the whole foliage-bearing surface must be removed, leaving only the bare trunks, and these trunks must be treated with a thorough coating of whitewash, composed of quicklime slaked with water.

It is recommended that the stubs of such trees, from which the limbs have been removed, be protected with an application of grafting wax or of paint to prevent the entrance of air and to save the tree for the growth of the new top. In the case of smaller shrubs and plants the total destruction of their tops at the ground will be necessary.

With the notice is also a special notice to the commissioners of Yuba County to thoroughly clean up the city of Marysville, before July 8.

This is drastic but necessary to the welfare of the State.

BE CAREFUL AND CONSIDERATE.

The Cultivator is growing so fast every way, that it is impossible to avoid mistakes. We aim to do this as far as we can but we do not always succeed. With TWELVE THOUSAND and over different names on our subscription lists and a large amount of daily mail to handle errors will be made. Certain things help mix our correspondence and contributions. Some folks fail to sign their name; others fail to put postoffice on the letter or article submitted; some write so we can't read the name or postoffice. The result is evident. If you fail to get reply to a letter or fail to get credit for a contribution don't blame us until you are sure that we had the above points to work from.

Our mail goes through many hands. If a letter contains a subscription, a query, a veterinary question, and a contribution or two and you sign your name and address to but one there is apt to be a mix up. Each part of the letter goes to a different department. No one reads the part belonging to another department and would not notice that address was missing. Once it has gotten separated there is no hope of finding the address.

We have made mistakes through the carelessness of printers and others that misplace names in type, and no one is the wiser until some one complains. We have many people working and it is not to be wondered at that some mistakes get in the paper and in the subscription lists.

If any one has discovered a mistake of name or address, or we have failed to give credit we would be pleased to get knowledge of the fact. It is'nt necessary to write an abusive letter for we are not in the habit of making mistakes purposely.

END IN SIGHT.

The Jamestown exposition is reported to be a financial frost. This leads to the expression of pubic sentiment which has been crystallized for some time that these hurrah expositions have about run their course. The Philadelphia fair, the Chicago exposition, the Omaha show, the Portland exposition were all difficult propositions to finance and in the end were profitless, so far as results went—except to the railroads which hauled the people back and forth. These expositions do not avail the country anything of value. Each one costs the government from one to ten million dollars and the treasuries of contributing states as much more. The system has taken on the form of an endless chain and a good deal of boodle and favoritism is passed around Congress every time one of these fool expositions is proposed. The fad has worn off and people are satiated, but after all it would seem too bad to cut the poor railroads out of such a big slice of their passenger traffic. The same money expended in legitimate endeavor to advance the agricultural and industrial conditions of the states in which these expositions are promoted, would result in vastly greater beneficial results to the country.

CHANGE IN OWNERSHIP.

Henry Kruckeberg has acquired the Rural Californian from Mrs. C. M. Heintz and the June number is a masterpiece in typographical beauty. The contents of the magazine is excellent as well. Mr. Kruckeberg formerly was connected with the Rural Californian. He comes back to his first love with enthusiasm and a laudable ambition to rank all monthly publications of like character in California. We trust he may realize his endeavor.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

San Fernando has a rural postal delivery.

Tomatoes are being shipped in carload lots from the Coachella valley.

A big plantation of Eucalyptus trees is being made in the Yucaipe valley.

The acreage of alfalfa is much larger this year than heretofore at Hemet.

The Farmers' Club at Mound held an interesting picnic last week at Casitas.

There are forty-five miles of distributing flume line, without the main line, on the Hemet Tract.

A stallion said to be worth $1000 belonging to a Huntington Beach farmer died of lockjaw last week.

The United States government Land Office in Los Angeles is being crowded with business as never before.

The Riverside county supervisors are to build a dipping vat in districts where Texas fever prevails.

The Auburndale Development Company at Corona has just completed the installing of a fine new pumping plant.

A veterinarian of Riverside county had his salary lowered by the county supervisors, from $100 to $50 per month.

The Laguna dam in the Colorado river above Yuma came near being washed out during the recent high water.

San Jacinto reports alfalfa fields in most flourishing condition with promises of $8.00 to $10.00 per ton for the output.

Riverside advertises several tons of straw at $1.00 per ton. San Francisco advertises straw at 70 to 90 cents per bale.

An alleged grafter by the name of Watkins has been called to book for a big land scheme in the neighborhood of Rialto.

The dairy business is on the increase at Hemet, and a large quantity of cream is shipped daily to Arlington and other points.

Onion growers of the Thermal Union are receiving two cents per pound for onions shipped from the Union, the total output aggregates over 35 cars.

Limas are now quoted at 5 cents per pound in Ventura county bean fields which makes the bean growers look sorrowful because they have none to sell.

Hay buyers are numerous amongst the ranchers back of Redlands. One trouble has been to secure sufficient hay balers to properly care for the large output.

Engineer Grumsky of the Interior Department is in Imperial valley looking for a satisfactory solution of the problem of the permanent control of the Colorado river.

The Pioneer Truck Company of Los Angeles owns a ranch near Chino where it pastures its stock and grows most of its supplies. There are over 5000 acres in the ranch.

During the recent high water of the Colorado river, the Southern Pacific kept a large force patroling the levees, also long trainloads or rock with engines ready for use in case of any threatened break.

HORTICULTURE.

Cantaloupe season is in full swing in Imperial valley.

Shipments of oranges from Riverside exceeds 5000 cars.

Etiwanda's grape crop this season is the best in many years.

San Fernando reports the earliest shipment of apricots for years.

Contractors are already in the field buying Etiwanda wine grapes.

The first watermelons in Imperial section were shipped last week.

Orange ranches are in keen demand in Riverside real estate market.

Tomato prices have ranged high in all shipments made from Brawley.

Riverside Horticultural Commissioners are making strenuous fight against red scale.

Highlands reports the biggest orange setting and promises for heavy crops for two years.

Riverside Enterprise reports certain vineyards of that valley showing immensely heavy crops.

Geo. L. Campbell has planted on his ranch near Silsbee, cuttings of the Black Morroc variety of grapes.

Apricot growers in Escondido have been selling apricots in carload lots at four cents per pound f. o. b. cars.

An incendiary attempted to burn the cantaloupe packing-house of the Brawley Fruit Growers Association last week.

Highland orange growers report the young fruit to be larger at the present time than ever before this early in the season.

Geo. Harold Powell lectured before Corona orange shippers last week giving information regarding better methods of handling fruit.

Four outfits are working in Riverside citrus orchards with the assurance that before this season closes the scale will be freed from their orchards.

Professors Steubenrauch and Eustace are visiting various citrus sections of Southern California with information as to the prevention of orange rot.

Cantaloupe output is expected to be lighter from the Imperial valley than first anticipated. It is estimated that Imperial will receive from $150,000 to $200,000 from this one crop.

J. W. Mills, in charge of the Citrus Experiment Station at Riverside, is making a number of interesting experiments, which it is hoped will be instructive, in fertilizing citrus trees.

The bringing of purple scale infested fruit into Redlands which was mentioned in the recent Cultivator, has caused Redlands people to be on the alert regarding any further shipments to that community.

The Santa Fe R. R. Co. has constructed a $4000 pre-cooling plant in its yards at San Bernardino. The plant will be in the nature of an experiment, and if successful, icing will in the future be unnecessary.

G. Harold Powell has gone East with his family and will later return to Northern California and investigate deciduous fruit decay. The next orange shipping season will find him in his same work in Southern California.

Northern California

AGRICULTURE.

Shasta county has harvested a fine crop of hay and grain.

Sierra valley in Plumas county reports big crop of hay and grain.

Some of the country press are calling attention of their subscribers to the anti-docking law.

Ukiah farmers are moving to establish a creamery at that place. A $10,000 plant is in anticipation.

Irrigation development in the neighborhood of Colusa is promised to bring that community more to the front than ever.

The trustees of the city of Porterville are merciful to the beasts of that section and are erecting water troughs by the roadside.

The Board of Supervisors of Sacramento county are making an extensive experiment in tobacco culture on the Colony Farm.

A. E. Boyton has begun a legal battle for all the farmers of the State to have a chance to purchase San Quentin grain bags.

Work of "unwatering" of Woodward Island near Stockton is progressing and already much of it has been planted to potatoes.

With an expense of the State Administration more than a million more than last year, farmers can count on a big, stiff tax this fall.

Modesto district reports great quantities of sweet clover, Melilotus alba, infesting the alfalfa fields, claiming it to have been brought in by foul seed.

Chas. J. Brand, specialist in the departement of agriculture of alfalfa, with other agricultural experts are visiting various points in the San Joaquin valley.

Hay press men in the neighborhood of Hollister are facing a shortage of baling wire. Even the San Francisco market is said to be clear of this commodity.

San Jose reports the hay crop to be exceedingly fine though somewhat short of the average. The Volunteer crop is reported as making a fine salable quality.

A scrap is on between the irrigators and a large power company, both claiming rights to the waters of Hat Creek near Redding. It is claimed the suit will be fought at every stage.

The Modesto Canal is carrying at this time 460 cubic feet of water each second, while 700 cubic feet flows through Turlock Canal. This is greater than last year's water supply for those districts.

The sheepmen are still urging an appointment of an inspector, but Gov. Gillett insists that until the funds to pay for these inspectors are forthcoming from the sheepmen he will make no appointment.

Australian rye grass for a foraging plant is proving to be very satisfactory in the neighborhood of Visalia and Tulare. Seed which was sown last December is giving grass which stands as high as a man's hand now.

A couple of farmers at Visalia are having a legal tout over one of them "stealing his own calf." The animal had been placed in pasture and was being held by the pasture owner for the payment of the pasture bill.

HORTICULTURE.

Nearly 40 cars of Valencias have been shipped from Lindsay.

Dried peaches are promised to range above ten cents per pound for choice lots.

Offers of twenty-five cents per pound have been made for dried apricots in Kings county.

Levee District No. 10 near Marysville is improving its levees by raising them an average of about three feet.

Seven thousand carloads of green deciduous fruit are promised as a total output of the northern end of the State.

Prune buyers are offering all the way from three and one-half to five cents basis on purchase for the coming crop.

Another boost has been given to raisin prices, being quoted at Selma last week at five and one-half cents per pound.

Orange planting in Orosi is being extended. This movement has been encouraged by the development of several strong wells.

Watsonville is making a heavier fight against the codling moth and claims the fruit will be finer there than for some time.

Fresno county has an acreage of 35,000 acres devoted exclusively to wine grapes, and 60,000 acres devoted to raisin and table grapes.

The total shipment in carload lots of deciduous green fruits from Vacaville this season is about five cars less than last season same date.

The rain precipitation at Sacramento in the storm of last week was .83 of an inch which is the highest for June since the big rain of 1884.

The peach crop of Yuba City will be about fifty per cent of the usual yield. The prices talked of are from $50 to $70 per ton for choice clings.

The State engineers will soon call a meeting to discuss and map out needed improvements in the levee system of Sacramento and San Joaquin delta.

Over ten cars of deciduous green fruit have been shipped from Cordelia near Vacaville. The output is said to be exceedingly satisfactory to the producers of that section.

Prof. M. Freeman, an expert on cereals in the department of agriculture at Washington visited the State recently calling upon Prof. Wickson of the State Experiment Station at Berkeley.

A Cultivator representative at Dinuba says that buyers there are offering five and one-half cents for raisins, 11 cents for peaches and 20 to 25 cents for dried 'cots and that all crops are looking well there.

The committee appointed by the Watsonville Chamber of Commerce to look into the matter of a district fair is still working with the expectation of having one soon. The committee wishes to obtain a portion of the State money for this purpose.

The untimely rain which was very heavy over the entire northern end of the State last week did far more damage than good, grain and cherries especially suffering. Some places reported as high as three-fourths of an inch to one inch of percipitation.

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis Worlds Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.

"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Profit in the Poultry Yard

We solicit short articles of a practiced nature from the fancier and utility breeder, giving their experiences with poultry. All inquiries pertaining to feed, management, disease and its prevention, will be answered through these columns.

WHITE PLYMOUTH ROCK.

WHITE ROCKS have attracted more attention in the last few years than any member of the Rock family. There is a cause for this, for no breed will continue to grow in favor unless they have utility as well as fancy. Several years ago Mr. Grant Curtis, President of the American Poultry Association, predicted that the next five years would see the "White Rocks" gain favor as they never had done before. We wondered why Mr. Curtis had said this for he was not a breeder of this variety. The remark caused us to pay more attention to the White Rock and study its practical characteristic. Today we find the White Rock has grown in favor with the fancier, also the utility man, until they have in many sections headed the list of Plymouth Rocks and, in fact, at many of the larger exhibitions they head the list of all varieties.

First Prize White Rock Cock
At Los Angeles Show, 1907.
Owned by Mrs. Amelia Sly, Hollywood, Cal.

History.

There is perhaps less doubt as to the origin of the White Rock than with their brother, the Barred. We say brothers for Mr. A. C. Hawkins claims to have started his strain from sports from Barred Rock and that he has kept them pure to this day day. But many claim, and we believe without good grounds, that there was White Leghorn and White Cochin blood used in their makeup. We believe that they originated from the Barred variety, for we know even in the oldest varieties of black fowls, even the Black Spanish, which is perhaps the oldest pure variety, that they occasionally threw white sports. This is due to a weakness in color vigor; the albino not having the quality of secreting the pigment which colors the feathers.

Years ago some claimed, and in fact do to this day, that a white fowl was not constitutionally as strong as a dark one, but this is purely a fallacy, for the White Rock is as vigorous and healthy as the Barred or any member of the Rock family.

A Scene in the Yards of Mrs. Amelia Sly
White Rock Specialist, Hollywood, Cal.

One point argued by many that there was White Leghorn blood introduced into the makeup of the White Rocks, is the fact that they are the best layers of the Rock family. While this may seem true, it is not necessarily so, for by careful selection the egg yield can be increased, and in breeding a white bird we believe that the utility purposes can be guarded better, as so much does not depend on color as in some of the parti-colored varieties.

Utility Qualities.

Had it not been for the utility qual-

ity of the White Rock, it would have been discarded long before it was perfected into the beautiful symmetrical fowl that it is today. We well remember when the White Rock was not a beauty from any point of view, but it was taken up by careful breeders and fanciers, who were determined that they would perfect it as other breeds have been. Today it will show kind treatment quicker than any fowl, which only proves for them that it has been bred to a very high degree, just as a thoroughbred horse will show kind and gentle treatment.

The White Rock is one of the easiest birds to breed up to and over standard size, which proves again that they are hardy, vigorous and constitutionally strong, or we could not push them above standard weight.

As layers they are all that could be desired as they mature very rapidly and the pullets begin to lay early. They are good sitters and kind mothers.

AROUND THE YARDS.

Table scraps are good for either old or young stock.

* * *

Never feed musty food, if you wish best results.

* * *

Watch the youngsters, as a little neglect will spoil a good prospect.

* * *

At this season you should give particular attention to the sitting hens. Keep them well dusted with a lice powder. Should you let the vermin get a start you will have much trouble getting rid of them.

* * *

The first year that we used trap nests we discovered that about one-fourth of our flocks were not worth breeding from. The next year we secured 20 per cent more eggs with 25 per cent less hens—we bred only from the cream.

* * *

Advice is the cheapest commodity on the market and worth as much to the one receiving it, so beware of the fellow that tells you there is millions in the chicken business. Experience is the best teacher and one that never deceives; also remember that labor has sure reward.

* * *

"Isn't an old gobbler about the most aggravating thing on a farm? If you start up a long-distance conversation with your hired man, the gobbler is sure to chip in and punctuate your remarks with his gobble, gobble, gobble. I believe it was that which taught me to swear. Being a family man my swearing is, of course, done in silence."

* * *

Infertile Eggs.

I recently set five hens from which were hatched just one chick. Have one large, lusty male with about 14 hens. His comb is red and he has every appearance of health and is now nearly two years old. Hens large fine birds that have never been sick. Feed principally wheat and table scraps, occasionally corn and Kaffir corn. One suggestion which has been made to me is that one cause of the infertility is that the yard is on a steep hillside with practically no leved ground. I considered it ideal on account of its gravelly nature and perfect drainage. But, tell me, does the steep hillside prevent the male from fertilizing the eggs?—M.

This in entirely new to us as we had never thought seriously of the above problem until it was sent to us. However, we believe that a very steep hillside certainly interferes with the male fertilizing the eggs.

We wish Mr. M. would place two or three hens that are laying, with cock either in a level yard or if he has no level ground, place them in the hen house for a week, set the eggs and furnish the Cultivator with the results. We would also like to hear from readers of the Cultivator who have had hillside experiences.

* * *

Turkey Troubles.

Will you please tell me what is the matter with my turkeys and what to do? They are just beginning to lose the down on their heads and get those red bunches like the old turkeys and seem to be in perfect condition, but every once in a while one will seem to be taken with cramps. After the cramps they seem to be paralyzed and lose the use of their legs. They will sit around for a day and then die. They have plenty range of both barley and alfalfa; also feed them dry curdled milk and chick food with plenty pepper.—L. J. D.

You are doing wrong by feeding your turkeys pepper. I sould say that they need no stimulant this time of year, but they do need grit, good sharp grit, constantly before them, and unless they have it will have indigestion. Another thing: You must look well for lice, head lice; one head louse will kill a fowl at this age. Charcoal should be before them also as it aids digestion. Also, don't feed young turkeys too freely. They will kill themselves on too rich diet.

* * *

Egyptian Corn.

I wish you would give me your opinion through the medium of the journal on feeding and analysis for poultry of Red Egyptian corn.—A. Subscriber.

For feeding properties and the analysis the Red Egyption corn is the same as the white, only poultry will not eat it as well as the white. For further information and an analysis of the Egyptian we would refer you to the Agricultural Experiment Station at Berkeley, as we understand it has made a thorough test of it.

* * *

Does It Pay?

Please let me know what you consider the best book on poultry raising for a beginner and what the present conditions are in Southern California with respect to poultry raising. Does it usually pay when conducted on a small scale?—J. O. V. B., Brooklyn, N. Y. City.

Your last question as to the probability of success in the poultry industry, when conducted on a small scale in California, is a rather broad one, and can only be answered in a general way. The opportunities for success in the poultry industry are the same in California as in any other State, and in the final analysis of this question the answer narrows down to the fact that it all depends on the person who is making the attempt. California climate and food products in the way of green food the year round are great helps in the poultry business here, as well as the high market prices for poultry and eggs. The poultry business is one that can stand an addition quite to the number of producers before it will become over-done in this section of the country. "Poultry West of the Rockies." In our opinion this is one of the best books on poultry raising.

Love usually tries to hide its noblest deeds.

Until the Chicks are over half grown, feed them dry

West Coast Chick Feed

Bright, pure, clean, made of the finest grains, seed, meat, etc., in just the right proportion to make a full rightly-balanced ration. They like it, too, and eat it up clean, for it contains no waste whatever. It keeps them healthy and wil make them feather faster, grow faster and larger than will any other feed. They need nothing else until over half-grown. If your dealer does not keop it, and will not get it, send $3.35 for 100 pounds, freight prepaid by us to any point in California.

CARE AND FEEDING OF CHICKS.

Acting on the invitation of the Cultivator to give experiences and points on breeding, Mr. Wheeler, of Perham & Wheeler, the Black Minorca breeders at Lordsburg, sends in the following timely article. Some day we hope Mr. Wheeler will give us his opinion of the Black Minorca as a money-maker.—Editor.

The Parent Stock.

Success in growing chicks very largely means success in the poultry business. This is the great battle ground and victory here means triumph all along the line. Chicks properly hatched, well-fed and carefully reared, kept ever on the move upward to final maturity, make the hens that lay a profitable number of eggs and keep the wolf at a respectful distance from the door.

The proper time to commence caring for chicks is before the eggs, which produce them, are laid. Keep the parent stock healthy and vigorous by giving plenty of good nourishing food, well balanced and of wide variety, combined with an abundance of green food, fresh air, pure water, and besides, don't fail to keep them busy, free from lice and in clean quarters. Hens are very much like other folks; they appreciate variety, and unless they have it, their appetites clog and the result is a falling off in egg-production and a lowering of vitality, which means weak germs and consequently weak chicks. Of more importance than the care of the hens is the care of the male bird. Remember he is "half the flock." The strain of breeding tells more quickly upon him than upon the females. The male should be given all he can eat two or three times each day, and for this purpose it will be found necessary to put him into a separate coop while he is eating. This may seem to be a great deal of trouble, but it will lighten the burden of caring for the chicks, as they will be much stronger and a large part of the causes for discouragement and failure will be removed.

The Brooder and House.

A great many chicks are killed in brooding. This is due to several causes: Improper ventilation, too much or too little heat, filth, lack of exercise and injudicious feeding. We use individual brooders heated by kerosene lamps. They are more trouble than a continuous brooder, but the added health of the chicks more than justifies the extra care. A 100-size brooder for 40 or 50 chicks is best. This brooder is placed in one of our colony houses, whose floor space is 4x7½ feet; 2 feet high in rear and 4 feet in front. The ends and back are perfectly tight to prevent draughts; the front is made of lath placed 1 1-4 inches apart with a 12-inch board at the bottom to prevent the chicks running out while small. A buralp curtain is arranged to cover the entire front of the house at night and on cold days while chicks are very small. When not in use this curtain may be thrown back onto the roof and the sunshine will flood the entire house, destroying disease germs and sweetening the interior.

As the house has no floor, it may be moved to prevent the grounds be coming filthy and also affording a fresh run. No outside run is necessary, for when the curtain is up, as it is unless the weather is very bad, the chicks have all the benefit of being outside, yet are protected. After the first week the chicks may be allowed to run by removing the 12-inch board at the bottom.

The brooder should be thoroughly cleaned each day. When chicks are a week old, the brooder should be placed in the sun five or six hours a day; this will reduce the mortality of the chicks fully one-half. While chicks are too young to be without heat so long remove the hover for a little sunning several times a day when chicks are feeding. The floor of brooder should be covered with fine sand to prevent excrement from sticking, also to take up moisture and odor.

Feeding.

We are firm believers in dry feeding as being the most satisfactory and successful method. There are a great many chick foods on the market and one should use great care in selecting, as all are not reliable. It will be found beneficial to have the floor of the house well littered with cut straw and to scatter the chick's food in this to induce the little fellows to exercise, for exercise means life and health. After chicks are thirty-six hours old, give them a very little chick food every two hours. Continue this process during first two weeks, then food may be safely kept before them on free range; but if yarded, feed about four times a day, all they will eat up clean in ten or fifteen minutes.

Keep fresh water, granulated charcoal and some kind of green food, such as lettuce, lawn clippings or chopped cabbage always before the chicks. Sour milk will be found an excellent addition to the other food and is much relished. Do not feed sweet milk, as it causes bowel trouble.

Cared for in this manner and allowed free range when possible, chicks will be healthy and strong, things of beauty and a joy forever.

Weaning.

Gradually reduce temperature of brooder from 85 degrees to about 65 or 70 degrees which will be at end of fourth week. Then unless the nights are very cool give no heat at all. Remove brooder and make roosts by using 3 pieces 1 r3 inches two feet long; set on edge with five 6-foot laths nailed across them 4½ inches apart, making a frame 6 feet long by 2 feet wide. Chicks will soon take to this roost and you will have no trouble about crowding. Do not be afraid of crooked breasts. Good strong, vigorous chicks seldom have crooked bones and the added growth and health of the general flock will more than offset the few crooked breasts caused by early roosting. When chicks are eight or ten weeks old take out the cockerels which will leave about the required number to a house.

When chicks are about three weeks old give them a mash in the morning consisting of three parts bran, one part middlings, one part corn meal, one part oat meal, one-fourth part beef scraps, two parts alfalfa meal or green alfalfa cut into one four-inch lengths,one-half part charcoal, a little salt. Moisten with milk if possible, or water, using but little moisture as chickens do not want slop. Make use of a great deal of energy in mixing and it will take less moisture. This feed should be cleaned up in five minutes. Gradually replace chick food with three parts each of whole wheat, Egyptian corn, cracked corn and two parts oats, either rolled or steel cut. Do not feed a great deal of meat. For our part we do not want our young stock to have all the beef scraps they can eat as it brings them to maturity to soon.

There is a great deal being said nowadays about early maturity, but we prefer the pullet that lays at six and one-half or seven months as a breeder, rather than the one that lays at four and a half or five months. Take a pullet fully matured, filled out in all proportions and when she does commence to lay she has the size and constitution to keep at it about 250 day in the year; her eggs will be large and her chicks strong. On the other hand, the pullet that lays in her babyhood never develops properly and will always be small. Feed to grow bone and muscle the first five months and the egg production will take care of itself. Of course, in our breed we desire large combs, but since the comb does not grow materially until the bird enters upon its final stage of development we want to postpone this last stage as long as possible in order to secure great size and strength. When nearly grown we feed a great deal of meat so that the comb develops very quickly and is quite as large as it would have been had the birds had meat during entire growing period.

Shade.

At this time of year, shade is a prime necessity. Chicks may be raised all summer if one has plenty of shade and takes pains to supply fresh green food. Be sure to keep your coops clean and disinfect them once a week with stove distillate and crude carbolic acid. This will keep out mites, lice and prevent diseases.

Finally, do not harbor runts; kill them and you will soon build up a strong, vigorous flock.—H. A. Wheeler.

THE DESERT.

Here is the ancient kingdom of the sun,
This barren, lowly waste of desert land,
Which for his own long years ago he won
And fiercely guards with flaming sword in hand,
Whose lightnings search the plain remorselessly,
Till all therein is tuned to flame's bright key.

His floods of light effulgently enfold
The plain with airy scarves of amethyst;
The ruddy earth and sands of tawny gold
Loom out like bands of flame through lilac mist;
Bright islands in the all-pervading flood,
The splintered porphyry rocks gleam red as blood.

The rainbow-haloed umber moon at night
Creeps in the upper dessert shyly past;
The stars, like myriad points of orange light,
Peep through the purpose shadow dim and vast;
And night and voiceless silence sit and brood,
Twin regents of the unbroken solitude.

Around this hermit kingdom thickly set
The patient hills in bony ridges stand,
With here and there a sentinel minaret,
Its feet deep planted in the burning sand,
Upon whose head, to whet his subjects' fears,
The braggart monarch rains his shining spears.

—Millard F. Hudson.

PLAN FOR COUNTY EXPERIMENT STATIONS.

A bill has been introduced into the Missouri legislature which authorizes any county court, on the petition of 50 freeholders or the resolution of any agricultural or horticultural society in the county, to establish and maintain an experiment station. This may be located at the county farm, or other land may be leased. Supervision is to be vested jointly in the county court and the State experiment station, and the work proposed is mainly that of demonstration.

United States Attoroney Lawler, of Los Angeles, has begun suit against the railroad companies handling cattle in Southern California and Arizona, because of alleged cruelty to stock in keeping them in cars 36 to 72 hours without water.

The owners of a packing-house of the Rialto Orange Company have begun suit against the California Citrus Union for $7720 because of an alleged negligence of the Union in causing the fire which destroyed their property a few months ago.

IT'S PENNY WISE.

Policy to set out a good tree, costing good money and then let the sun burn the bark or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Manufacturing Company, 2124 Willow Street Los Angeles.

Winters shipped her first full car of deciduous fruit last week.

Bees and Their Care

LOCATION OF THE APIARY.

A WRITER in Coleman's Rural World in speaking of location of the few hives which may be kept near the house says:

Perhaps the first consideration with small beekeepers is to have the hives within easy view of dwelling-house windows, so that issuing swarms may readily be seen from kitchen and living rooms. When only a comparatively small number of colonies are kept it is not necessary for one to be constantly in the yard, unless the apiary is so located that swarms cannot be seen from the dwelling. Time is valuable, and particularly so at the season when swarming is in progress, hence the beekeepers desire to avoid spending time watching for issuing swarms. Therefore, when it can be done, the hives should be set within view of the kitchen and dining room windows.

Not Near Road.

But, while this is advisable, too much cannot be overlooked in setting them there. Bees should never be set near much-used entrances, or near drives and public highways. Nor should they be set where it will be necessary to frequently pass before or between the hives in going to and from the house.

The hives, for the good of the bees, should not be set up against or even before the south side of buildings and dense shrubbery. Nor again on steep south slopes, unless shaded from the mid-day and hot afternoon sun by trees or shrubs. One is tempted to give the bees the benefit of the protection and warm sunshine thus insured, but nevertheless it is a misguided kindness in the end. Later, when the midsummer sun beats down upon the hives, the combs will be likely to melt down and both honey and bees lost.

The Best Place.

Perhaps the best location, when at hand, is a gentle eastern slope protected from hard winds by some kind of wind-break. In a place of this kind shade will not be necessary, although if a few low-growing trees or shrubs are there it will be well to take advantage of their shade during the heat of the day.

Hives may be set with entrances facing south. On strong southern exposures, however, set entrance to the north or northwest. The bees will be less liable to come out cool days, will not hang out so badly nor swarm so persistently, and will be less likely to abscond when newly hived. On western or northern exposures the entrances should face to the east or southeast. On the level they may be set to the south or southeast as is most convenient.

There is one thing in connection with the location of an apiary not usually taken into consideration, and yet which is of more importance than would seem at first. This is the condition and preparation of the ground.

Before undertaking to establish an apiary it would be well to plow and level the plot intended for a bee yard and then sow to some low-growing grass. Then set the hives in straight rows, two in a place, with fixed spaces between, so that a lawn mower could be used both between rows and between pairs. It would then be a comparatively easy matter to keep down weeds and to always have the yard in an attractive condition. Besides the unsightliness of an unkept yard, it becomes difficult to get around in going to and from and among the hives after a high growth of grass and weeds takes possession of every available nook and corner. Again, grass and weeds choke up the hive entrances to such an extent as to seriously impede the progress of the bees in going from and entering their hives. After, however, an apiary is once established in a certain place, it is often next to impossible to move it, even for a single season, therefore one must grapple with the weed problem as best he can. Usually, by arranging the hives as outlined above, it will be much easier to keep down weeds than where they are set about without regard to system.

But, aside from the great advantage of having the hives arranged orderly in regard to keeping down weeds and grass, it is better for other reasons to have them so. In the first place, it is more convenient to work with and over them, and further, records are more easily kept. Then, too, it looks so much better that instinctively beholders are at once impressed with the neat appearance of the apiary and imbued with respect for the bee-keeper and his vocation.

Generally, the first thing in taking off honey is to smoke the bees. A little smoke will drive them, while too much only confuses. Use just enough to divert the guards at the entrance of the hive.

HONEY PROSPECTS.

"The season is practically a failure in Southern California. Some of the largest producers in the vicinity of Los Angeles report no honey in sight, and are feeding. While there were good rains, yet subsequent weather conditions prevented the bees from doing much. While some sage honey will be produced in the extreme southern part of California, we are safe in saying that very little of it will find its way to any of the Eastern markets.

"Conditions have not been altogether satisfactory for Central California, and we do not expect, therefore, much of a crop from that section.

"Weather conditions have improved somewhat for the Northern States; but the season as a whole is still very backward. In many localities the bees are doing exceptionally well in making up for bad weather. Dandeloins have yielded honey and pollen as never before; and where there has been any fruit-bloom the bees have done well. Clover and basswood have been put back a couple of weeks; and if they do not come on too early there will be a chance for a fair crop, for the bees are now making double-quick time.

"The spring losses, however, have been very severe all over the country, south as well as north. The Southern States seem to have suffered more proportionately, as they were not as well prepared to stand the bad weather as their more Northern neighbors.

"Texas is not saying much, but the few reports are not particularly favorable. In Colorado, conditions have not been satisfactory; and the season in Florida has been a complete failure.

"There ought to be a strong stiffening of prices, for the market certainly will not be glutted with honey, and there will be very little glucose concoctions on the market masquerading under the name of honey to hold down prices. We look for a better market than we have ever seen before."

The above is from Gleanings, in Bee Culture, and makes things look blue for the California apiculturist. Much more so then the Californian is willing to concede. However, making some allowance for desire to bull the market it may be admitted that California will not have as big a crop as she may desire. But when it comes to "A very little, if any honey will find its way to any of Eastern markets," then our Eastern friends have another guess coming.

HOW BEES DIVIDE LABOR.

My experiments have revealed the fact that the division of labor among bees is carried to a surprising extent, says Proffessor Gaston Bonnier.

Bees which are seeking for pollen or nectar do not carry it, but merely carry the news to the hive.

A number of bees are sent out to strip the flowers, a number carrying pollen only, others nectar only, others again water only when water is needed. The number sent out is proportional to the number of flowers to be stripped, and by marking the bees with colored talc it was proved that each bee confined itself for the time being to one class of work.

The same bee might be seeking for flowers in the morning and collecting in the afternoon, but did not change the nature of its work without returning to the hive.

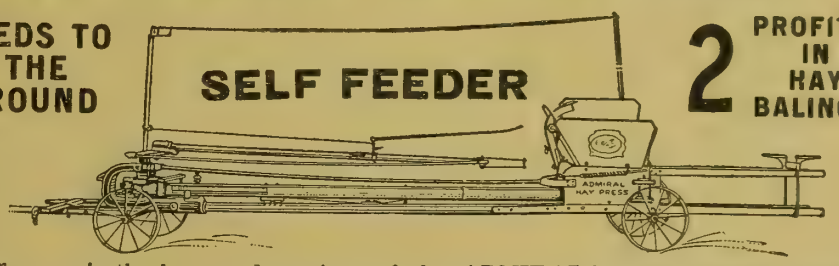
There seemed to be something in the nature of a working arrangement between bees of different hives, as when the work of clearing a certain area of flowers had once been commenced by a few bees from one hive these collectors were not interfered with by bees from other hives.—Louisville Times.

AN ADMIRAL WITHOUT COST

3 FEEDS TO THE ROUND

SELF FEEDER

2 PROFITS IN HAY BALING



The difference in the increased earnings of the ADMIRAL THREE-STROKE SELF-FEED PRESS more than pays for the press in one season, at a conservative estimate of 2½ tons per day over the old style two-beat, foot-feed press, besides the ease of labor on both men and team, and better work. Let us figure a little to convince you.

2½ Tons per day for one week, 15 tons at $1.50 net.....$ 22.50
One month's earnings over the other press (26 days)..... 97.50
On an estimate of five months' work out of the year..... ..... 487.50
The above gain with the ADMIRAL more than pays for the press.

Wire Worms.

I enclose a worm that is destroying all of our garden truck. Began with peas. When about 6 inches high they wilt and die; then the beans went, the melons followed, finally the sweet corn. I find the worm begins at bottom of root and eats out the center. I send one stalk to show how they work. Can you tell us what it is and how to destroy the same?—C. A. L., San Jacinto.

The worm is the common wireworm which is the larvae of the snapping-bug or chick-beetles of the family of Elatiridae. Many children have been entertained by watching these peculiar bugs. But the farmer whose crops are ruined by the worm or larvae of the bug is not amused.

The worm is long, narrow, wormlike creature, very even in width, with hard covering and brownish or yellowish white in color. They infest the roots of many grain crops and as our inquirer says his garden crops are suffering. When they attack the plant in its susceptible period they not only "suffer" but are killed.

Unfortunately we cannot suggest any very satisfactory remedy for, as Mr. L. says, the worm eats the heart out of the root thus making himself almost unget-at-able without destroying every plant.

Comstock says: "Although we tried an extensive series of experiments, extending over several years, we were unable to find any satisfactory way of destroying the larvae infesting field crops. But we found that if the cells containing pupae or recently transformed adults were broken the insects perished. We conclude, therefore, that much can be done towards keeping these insects in check by fall plowing; for in this way many of the cells containing pupae or young adults would be broken."

A subscriber says that with much prized plants, he has saved them by taking carrots and packing in large flower pots with moss, taking care that the small opening at the bottom is well open up to the carrot. The pot is then sunk in the ground near the plant to be protected. The wire worms will go to the carrot of which they are very fond, when the pot can be lifted occasionally, the worms destroyed, the old carrot replaced with fresh "bait" and the work repeated. But with field and large garden crops thorough and deep tillage seems the only remedy and that largely for next year's crop.

Veterinary

Answers by Dr. J. Oliver, 318 E. 2d St., L. A.

Injured Colt.

I have a colt which has run on pasture the last year when something happened to him; do not know whether a cow hooked him or if he got snagged or that an abscess formed on him from some other cause. When I found him he had a very bad sore on the inside of his left hind leg up as close to the body as it could be and not be on the body. I doctored him for a while trying to heal it up, but could not, so was advised to give him something for his blood, which I did, and he seemed to pick up in flesh while before he had none. The sore did not heal and besides another formed on the left hip just above the flank. Discharged for about two weeks and disappeared then another formed right in front of the first and a little back of the stifle joint. I have washed the sores with creoline and carbolic acid in warm water and injected it into the cavity.—Mrs. W.

I think your colt has either splinter of wood or foreign substance of some kind. You should have the parts well opened up where the abscess formed and thoroughly explored. Then use a solution of the following inserted in with cotton on syringe twice a day: Raw linseed oil, spirits of turpentine; of each 2 1-2 ounces, compound tincture benzoin 1 ounce, shake and inject.

Founder.

I have had two mares which were taken sick after foaling. They were running in pasture and the third day after they foaled they appeared to be foot-sore and stiff like they might have been foundered, and when they make an effort to move their muscles quiver all over, and are in a good deal of misery. They do not have much appetite and remain standing almost all of the time and appear to have cramps in the bowels at intervals; also some fever, and it seems very hard for them to pass urine. The passages from the bowels appear to be normal.

The first one taken sick has partly recovered; she has brought four colts in four years; would it be well to let her rest a year.—J. M.

Your mares are foundered. The fever after foaling or perhaps took little cold is cause. I have seen two similar cases this year. Give two teaspoonfull of nitrate of potash in mash or dissolved in water for the drink twice a day for a week if necessary. It won't be necessary to let mare remain barren for a year.

Disease of Dogs.

We have taken your paper but a few months and find it very helpful. Would like to know if you know anything about a disease the dogs get here in their heads; seems to be an itching and burning in the ears and head; later it gathers and discharges; also goes through the body. One dog's foot would gather and discharge. We have lost two and are told there is no cure for it; also that children might contract the disease from them. We would like to know as soon as possible through your paper, for other people are having the same trouble, and we have a dog now we are afraid is showing symptoms.—Mrs. H., Downey.

From your description I could not say what the disease is with which your dogs are affected. Foxtail getting in the ears cause a diseased condition similar to that which you describe. They fester and discharge offensive matter from ears and sometimes from body and feet, wherever they get into the animal.

Bad Breath of Horse.

Have a mare with a very disagreeable odor about her breath, seems to be worse sometimes than at others times. What should be done for same?—A. R. S.

Have her mouth and teeth examined; this is often the cause of bad breath. Beards or foxtail often work in under the tongue or between or on side of teeth.

Mange on Horses.

Another query comes as to remedy for mange on horses. This was answered on page 602 of issue of June 6. Dr. Oliver also says that a solution of phenol, 4 ounces to a quart of water is a good remedy.

Irrigation and Forestry

LIFTING WATER FROM WELLS.

IN encouraging its subscribers to secure irrigation water by pumping, the Deseret Farmer says:

"Where valuable crops can be grown and marketed profitably, pumping stations can be made to pay well. In California, where the land and the climate are specially fitted for fruit growing, and where well water can be had within 500 feet of the surface, such land is said to be worth $500 an acre."

Unless the type-setter added an extra cypher, we think the Farmer has another guess coming for we don't believe any crop now grown is profitable enough to stand up under a 500-foot lift of water. To pump water such a distance is very expensive. If it's 50 feet, then go to it for there's money in it.

Regarding the wells, the paper then quotes from a paper by F. H. Newell, as follows:

Surveying for Irrigation

The Well.

The most economical well for securing water in the quantities needed for irrigation is a well from 12 to 15 inches in diameter, extending into the water-bearing gravels 30 to 60 feet according to the thickness of the gravels at the place where the well is drilled. Strainers for these wells can be made of slotted galvanized iron. The perforated metal should be placed opposite all the coarse gravels, or at a depth of 10 feet below the surface of the water. These strainers can be made by any mechanic by punching 1-8x1-inch slots into heavy galvanized iron and then riveting the sheets into cylinders of the proper diameter. The cylinders should be rolled in such a way that the burr made by punching the slots will come on the outside of the finished casing, and so that the slots will be vertical.

A much better strainer can be made by purchasing the metal in sheets already perforated. For this purpose steel sheets 48x120 inches in dimensions, perforated with hit and miss slots, 3-16x1 inch, and galvanized after the perforations are made, will make ideal strainers. When rolled into cylinders these sheets form a casing about 15 inches in diameter. In constructing the well the perforated sections should be put in place, one above another, to within about 10 feet of the water-level; from this depth upward, the casing should not be perforated.

Distance Between Wells.

If it is necessary to construct several wells in order to secure the amount of water required for an irrigation plant, it becomes important to consider the best and most economical arrangements of the wells. Two different methods will be found available for this purpose. If the amount of water required is not greatly in excess of that which can be supplied by a single tubular well, it is often found practicable to construct a large dug well, 6 to 10 feet in diameter, to a depth of 5 to 10 feet below the water level, inserting in the bottom of the dug well several feeders of perforated galvanized iron, as described above. This method has the advantage of permitting the pump that is to recover the water to be submerged in the water of the well.

In order to sink a dug well the proper distance below the water level, it is necessary to construct a wooden, brick or concrete crib that will sink as the material is removed from its interior.

Another method of securing a large quantity of water is to sink a battery of wells and connect them by suction pipe to the pump. This method is adapted to secure a larger supply than the method just mentioned. Three or four, or more, wells can be arranged in a straight line, 20 to 30 feet apart, and connected to a pump placed near the center of the row of wells. Probably the most satisfactory pump for use in irrigation is the centrifugal pump.

Source of Power.

A popular source of power for small pumping plants is the gasoline engine. Where the price of gasoline is high, it is very easy to make the cost of water phohibitive by the use of such power. Whether or not it pays to pump water by gasoline is a matter which depends very largely upon the distance the water must be lifted, and also upon the kind of crop that is to be irrigated. Gasoline, even at a high price, is usually a cheaper fuel than coal in an ordinary steam engine of small horse power, such as a common traction engine.

How High Water May Be Lifted.

It is very unlikely that it will pay to pump water, under present conditions in the valleys of the western plains, to a total height of more than 30 feet, including the suction lift of the pump. If the pump lower the water in the wells 10 feet, and if the distance to water be 10 fet below the ground, and the discharge pipe be brought into a reservior or flume 5 feet above the surface of the ground, the total lift will be 30 feet, if 5 feet be added to cover loss of head due to friction in suction and discharge pipe. reservoir is absolutely necessary for best results with small pumping plants. If the supply of water exceeds 500 gallons per minute it is possible to dispense with the reservoir, especially if the supply greatly exceeds this amount. Plants furnishing over 1000 gallons per minute can usually be bost operated without the use of a reservoir.

THE WHITE FLY IN CALIFORNIA.

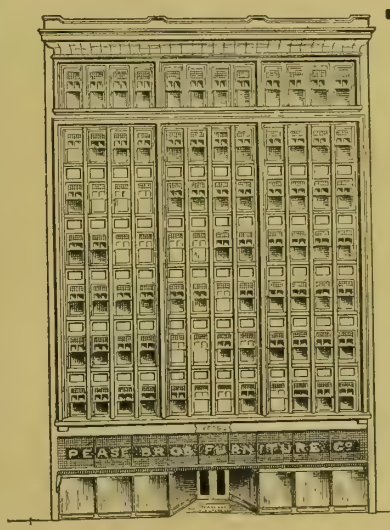
Continued from Page 643

is still confined to the city limits of Marysville. There are no citrus orchards in the immediate neighborhood. Possibly therefore it may not have reached any other section. If let alone it will certainly reach every part of the State. The trees in the immediate neighborhood of the railroad tracks are now infested. The electric cars pass between infested trees going to the orange orchards of Butte county. Now, if ever, is the time to make an effort to destroy the pest. There is no possibility of throwing a quarantine around the infested district that a flying insect will respect. To delay all efforts towards eradication till next winter, as seems now to be the programme, may be a fatal error. Every day during the latter part of the summer thousands if not hundreds of thousands of these minute creatures will be in the air capable of living long enough to be carried, in a car, the length of the State. A single one of these reaching a citrus district might make the eradication of the insect an impossibility.

In order to irrigate economically from pumping plants it is usually desirable to pump the water into a reservoir having a capacity equal to the amount of water the plant can furnish in six to eight hours. Such a bility. It may be that already the insect has gotten beyond control, but the chance of eradication is certainly worth the effort.

If eradication is to be attempted, no half-way measures like spraying or fumigation are to be thought of. There is too much oportunity to miss some and no means of discovering the fact. A campaign of eradication should include: first, the immediate destruction of every leaf on all citrus trees in Marysville and of every other plant known to furnish sustenance to this insect; second, a thorough inspection of the new foliage as it comes out on the defoliated plants; third, an exhaustive search for other possible food plants of the white fly; fourth, redefoliation and persistent reinspection of any spots where the fly may not have been annihilated; fifth, careful inspection of every supposed case of white fly in the State; and finally competent scientific supervision of the work.

There will be very few adult flies produced during this month and the early part of July. After that the em will be much greater and the chances of success corespondingly lessened. Will those most vitally interested see that the work is undertaken?



OPENING SATURDAY JUNE 22

The Largest and Finest Furniture Store on the Coast

After many months spent in the erection of a modern, eight-story and basement, reinforced concrete building, built especially to suit the needs of a large furniture, carpet and drapery business, the Pease Brothers Furniture Company will open its doors for the first time to the general public next Saturday. Music from 1 to 5 P. M. and from 7.30 to 10 in the evening. Remember the location is on Hill street near Seventh.

SURE CURE FOR PILES

ITCHING Piles produce moisture and cause itching. This form, as well as Blind, Bleeding or Protruding Piles are cured by **Dr. Bosanko's Pile Remedy.** Stops itching and bleeding. Absorbs tumors. 50c a Jar at druggists or sent by mail. Treatise free. Write me about your case. DR. BOSANKO, Philada., Pa.

Household Department

TELL YOUR MOTHER.

Tell your mother—have no secret
You would not to her disclose,
For her love would be no weaker
If all the world should be your foes.
Tell your mother—if some question
You are puzzled to decide;
She is older, wiser, calmer,
And will be your safest guide.

Tell your mother all your wishes,
All your plans and hopes and fears,
And you'll have much less of folly
To repent in after years.
Tell your mother, trust her counsel!
Rather than some young friend, gay,
Weary hours she's worked for—loved you,
Cause her not one anxious day.

Tell your mother—'tis a motto
Worthy every girl and boy,
And if followed, it will bring you
Pleasure sweet without alloy.
Then who'er be your companions,
In whatever place you move,
Let your conscience ever witness
"Mother knows and does approve."

—Selected.

THE FAITHFULNESS OF OLD DUKE

WHEN we are young and light-hearted, as well as light-headed in some cases, we take in strong likes and dislikes, of which afterward we are oftentimes sorry or ashamed. One of my dislikes was for dogs—just an imagined dislike and fear my only brother, who kept a goodly supply of hunting dogs, often declared.

But while I was yet a little girl baby my brother went away to a distant State to engage in business and there married and made his home. After some time we heard at the old homestead of a baby boy in his family, and three years afterward of his death. Several months after this sad tidings, a letter from brother came to me, asking if I would not come and take charge of his house for a while, as his wife had never been quite well since the death of their child, and he had finally persuaded her to go away to a famed mountain health resort. She would go provided I would take her place in her home, as she understood I was quite a notable little manager.

My brother's home was such a lovely one, with its outlying lands, bordering on the suburbs of a large city, and, as I entered its sitting room, I espied a long, low window in it that overlooked a scene worthy of the brush of an artist—a long vista of sloping lawn, its velvety green starred by clumps of radiant flowers, while fountains played in the golden sunshine, stealing through the trees above, and beyond the white highway, through the emerald meadows, a silver-tinted stream wound its way to the sea. "Oh, the beautiful picture!" I breathed, as I dragged a small rocker to the window. "I now and hereby lay special claim to this window as my own while I remain in this house."

"Something else has a prior claim on that window," spoke my sister-in-law from the divan on which she lay near by. "But he is kind and will allow you to share it with him. Poor Duke! He never forgets—no more than I do."

I gave little heed to her words, said with such a sad tone, but across the river had caught a glimpse of a man, young and handsome, as I could see even at that distance, going into a tiny white cottage nestled in the meadows. In his hand he carried a basket, and on his shoulder a fishing rod.

Who is it?" I asked "That cottage and those meadows belong to brother, do they not?"

"It is a Mr. Smith, who claims to live in the South somewhere. He rented the cottage for the fishing season. He comes up here quite often, and Arthur seems to have taken a liking to him because he has been everywhere and knows so much. You know your brother loves a race horse, and what an enthusiastic hunter he is. Well, Mr. Smith has the same tastes in these lines, and lots more experience in either than Arthur. And that constitutes the affiniity between them. But don't you go falling in love with him. He has beautiful eyes, and is very strong and athletic, but there is something about the lower part of his face that I don't like. His mouth is cruel, and his jaw too broad. Then, I feel this better than I can explain it, but I am almost sure that he is not an educated man. His way of saying things is so queer. Arthur thinks I fancy this and"—her words were interrupted by a great brown body swinging into the room and making straight for me. I screamed and clung to my chair. I thought I was going to be killed before the chair finally overturned with me, and I rolled out of contact of the big brute, and now placing himself comfortably on the rug beneath the window, after which he laid his huge head on the low window sill and scanned the driveway and road beyond it.

"Stop your screaming," my brother's wife said, now sitting up. "That is only old Duke, Willie's dog. I called to you to sit over and share part of the window with him. When they took our darling out of the house forever, Duke sat in this room and cried so mournfully. He watched them from that window go down the driveway, and now he lies close to it when in the house, watching for Willie to come back, we think."

"I can never, never stay in a house with such a dog coming and going at will. Ugh! The big, ugly, wild-looking thing!" I exclaimed, shivering and drawing away from that part of the room.

"We will never part from Duke," said my sister-in-law, quietly. "And he isn't one bit ugly. That dog would never let Willie out of his sight, and he saved his life twice that we know of; once from drowning and once from a mad steer that had broken loose. He is faithful to every inmate of this house. You will not be afraid of Duke when you are here awhile."

I made up my mind from the very start that I would not try to like Duke or try not to be afraid of him, and I made up my mind just as positively the first time Mr. Smith showed his goodly form and beautiful eyes in my brother's house, after my entry into it, that I was going to like him in spite of sister's forebodings that his character, because of that look about his mouth, was not all that it should be. I told her before she went away that she was full of fancies for Mr. Smith, who now called on us quite often, and whose manner toward me, when we were alone, was not to be mistaken. When she had gone some time, he said:

"I never saw a girl I thought quite so handsome, or liked as well as you. Do you love me?"

Somehow, for the first time, I felt that ring in his tone, that certain way of giving expression to the spoken words, that my brother's wife had spoken of. It jarred on my whole being, and I drew my chair away from the close proximity to the one in which he was sitting, as I answered:

"I am not going to marry until I am twenty-one. We will have plenty of time to get acquainted before that time, and there will be plenty of time for me to answer your question."

And then, as the words were scarcely spoken, girllike, I repented for my harshness, as I called it then. One day my brother said:

"Lily, I am going to see how Laura is getting along, for myself, and whether she is improving as fast as she thinks she is, or if it is just an excuse to get home. I may stay a week, and I want to tell you something, for I know your venturesome ways. You don't want to let Jake go away at night, and every night let Duke have free access to all the lower part of the house. There are burglars about our town—burglars who do not hesitate to take life, if detection is imminent. No burglar can get in this house if Duke is given free range in it at night. Now, remember this."

I thought of it just as long as he was telling it and no longer, but I noticed that after his departure Duke, who had seldom noticed my presence in the house, much to my horror, took to following me everywhere, and keeping a close watch over me. He was lying near me on the veranda when Mr. Smith called, the first evening after brother had gone. "I hate the very sight of that dog," I said, in a petulant way. " I wish he were dead."

"I fear him," said my visitor. "I am sure he hates me, and I am certain that he will try to kill me. He follows me almost every evening that I leave here, and more than once I have found him crouching ready to spring on me. What is the use of keeping such a wild beast about the house?"

"O, mercy," I said, in a fright; "If I thought that he would ever hurt you, I would poison him. Indeed, I would. Why can't you? It would soon be over. He is only a dog. I can never, never have any peace in this house while he is in it."

"You forget," he said quietly, "that the dog will not eat anything given him by a strange hand, but I can bring you something, if you say nothing about it, that will bring death quickly and painlessly. You can give it to him."

Besides myself and the cook an elderly woman, there were two other persons left in the house, the dining-room girl and Jake, her lover, who looked after the horses and yard. The next night Jake asked permission to go to a dance in town with his sweetheart, and I immediately said yes to that proposition. Very early the cook went upstairs to her room, leaving the house below to Duke, who seemed uneasy this evening, and myself. After dark some time Mr. Smith came for a brief call and, handing me something

done up in a paper, explained that it was a bit of fresh beef for Duke, and I threw it to the dog, and then turned away that I might not see him gulp it down. I heard him dart out of the room, and the house, as I thought, with it. And then I heard no more of him. Mr. Smith remained but a few minutes, scolding me gently, now I remember, for allowing Jake to go away, and helping me, as I supposed, to lock up the back part of the house.

When he had gone, although Jake carried a key to the front door, I determined to stay downstairs until his return, and after closing all the doors between the rooms lay down on a couch in a small room adjoining the sitting-room, and soon fell asleep, to be awakened after awhile by something moving stealthily in the next room. My heart almost stopped as I put my ear very close to the wall to listen. The sound was exactly like that made by Duke at times when pacing through the rooms. But Duke was lying outdoors, cold and dead, of that I felt sure. The sound continued, weird and ghostly. Silver-tongued and very costly clock chimed out twelve from the dining-room, and when it stopped I heard a faint click, click, following it. And now I sat up, trembling with apprehension that had nothing to do with the unearthly. My brother's house contained much of value worth carrying away.

I tiptoed my way to the dining-room, the door of which stood partly ajar, although I had surely closed it. The lamp was burning low and I was half way across the room before I noticed the plate piled in a heap on the table, and someone kneeling at the safe, the door of which stood open. He raised up, and stricken with surprise, I staggered back, crying:

"Oh, Herbert—Mr. Smith—not you—surely not you!"

He came toward me, a look on his face that turned my heart to ice. I sprang back, catching the knob of the sitting-room door, in desperate hope of finding safety that way; for I read his intention in that look. As my hand closed on the knob he caught my throat to stifle the scream on my lips, and I heard him mutter as a knife flashed up in the other hand:

"Dead, you cannot talk."

My grip on the knob turned it, and as I went back with the door, the knife missed its mark and came down on my arm. As it was again raised, something dark and ponderous sprang over me, with an enraged howl, and bore my assailant backward, bleeding from the white, sharp fangs tearing at his throat. That moment I realized that Duke was not dead, and the next, with my arms around his neck, I was pleading with him as though he was human, not to kill the man under him. And Duke seemed to understand and obeyed me, although he would not loosen his hold, after the cook had sent in a call for the police, and they had come, bringing a doctor to attend the wound on my arm, until I bade him do so. And then, though badly gashed himself by that horrid knife, he lay down by me, and watched the doctor bind up my arm.

With feelings of shame and thankfulness I can never forget, I found that meat under a foot-stool in the sitting-room, where Duke had made way, after I thought he had left the house. And there, lying by the window where I could not see him for the darkness, I had shut him in. How near I had come to death because of my disobedience and hard heart I never told for many a year afterward.

Mr. Smith proved to be a very polished but at the same time a very dangerous burglar, wanted in several places for greater crimes than burglary.

"And to think," said brother, "that I was so decieved in the fellow, even to the extent of introducing him to my home."

But you may know that I never let on that I had been deceived into nearly loving him. Duke knew it, but Duke, thank fortune, couldn't tell it. Did I love Duke after that? Well, you may know I did, when my brother's wife came back, fully recovered, and I went home, I insisted on taking him home with me, and, as Duke seemed to love me just as tenderly as he had loved Willie, she finally consented for him to go with me. I kept Duke as long as he lived, and I believe that my love for that dog taught me to love all things in a better way.

HOMELY HINTS.

Old fowls are made tender by adding two tablespoonsfuls of good vinegar to the water in which they are cooked.

For tin covers, etc., the following mixture is excellent: Shred half a pound of soap into a bowl with a large ball of pounded whiting, and add enough warm rainwater to make a paste of the consistency of cream. Take a little of this paste on a piece of clean flannel and with it rub the metal. When dry polish with a leather and a little dry whiting.

Every tea caddy should be air tight. Tea owes its flavor to fine volatile oil which is present in very minute quantities. If exposed to the air this volatile oil rapidly disappears and the tea at once loses its aroma.

Only a few people know that butter will remove tea, coffee or fruit stains. It should be rubbed on the linen or cotton and then the material should be soaked in hot water and a mild soap. In fact, any stain except ink yields to this treatment.

A good furniture polish consists of two parts of raw linseed oil and one of turpentine. Mix thoroughly by shaking. Apply a thin coat with a flannel cloth and then rub thoroughly and briskly with a dry cloth.

To temporarily stop a leak in a pipe, use yellow soap and whiting mixed into a paste with a little water. This will not prevent the necessity of a visit from the plumber, but it will enable you to await his coming.

If anything becomes sticky with flypaper, use kerosene oil to clean it off. It has done for everything we tried. I used it on a leather bound book; it removed the stickiness without harming the binding at all. Used it on book leaves, cloth, etc. Try it.

Many darn worsted stockings with worsted. This is a blunder, the consequences of which show themselves very rapidly. The worsted always shrinks, and then the darn is contorted and drawn up out of shape, to the wearer's distress.

Mildewed linen should be soaked for several hours in buttermilk and then washed in the usual way.

To clean a dirty boiler put about a pound of caustic soda into the boiler, nearly fill it with water and boil for an hour or more.

You need not be caught thirsty

APPELL'S
SOUTH AFRICAN
WATER BAG
(PATENT APPLIED FOR)

Keeps water cool 48 hours or longer; in sun or shade; no ice. It is a great boon to prospectors, surveyors, sportsmen, miners, travelers, rangers, stockmen, timber men, farmers, threshing crews, millmen, railroad men, teamsters, boatmen and everyone exposed to dry or warm weather, away from good water supply. It is strong and durable; light and convenient to carry over shoulder, hung on vehicle—any way, so long as bag is exposed to air. Satisfaction guaranteed or money back.

SIX HUNDRED FRUIT TRAYS FOR SALE cheap. Two by three; good condition. JOSEPH THORNDIKE, Pasadena, Cal.

The percentage of an average crop that may be expected this year in the Pajaro valley is placed by some authorities at 30 to 35 per cent Bellefleurs; 50 to 60 per cent for Newtown pippins, with about a like percentage as a whole for crop for other varieties. —Pajaronian.

San Diego county stock men have planned a meeting for the purpose of taking steps toward eradication of the Texas fever tick, which will be held at Escondido.

The Produce Markets

Los Angeles Markets

LOS ANGELES, June 19,1907.

While the market is not showing a weak tone, it may be said that a material shading in prices is observable. As the movement toward the beaches and mountain resorts sets in the consumption will decrease here and probably show a greater shading. One thing surprising is that eggs, even, took a tumble on Tuesday of a half to a cent. This is generally considered temporary though some maintain that the market had been bulled beyond legitimate conditions by speculators. But the warm weather probably had more to do with it than any other feature.

Butter.

Butter stands at last week's quotation and the market is very firm.

Benjamin Snow is suing the Dinuba Creamery Association for money which should have been received for butter sold to an insolvent Los Angeles dealer. The patrons of the creamery were receiving their pay on the basis of the selling price of the butter, but while the price at which the butter was sold was good, the money never being received, the creamery management claims to be exempt from making any payment on that particular cream.

Ex-Governor Pardee in accepting an invitation to address the people of Salinas on irrigation at their big meeting to be held June 27th commends them for the step they are taking to secure government aid in irrigation.

The bond election of the city of Los Angeles last week, at which time bonds for $23,000,000 was voted for constructing canal to convey Owens River to the city, was one of the most important events in Southern California in many months.

San Francisco Markets

SAN FRANCISCO June 18, 1907.

Butter.

The dairy market is quite satisfactory in the volume of demands, and the best grade of each kind of stock gives hint of the increased request by the slightly higher figures asked. The butter business is much more steady in the trading tone, although when taken in volume both the demand and rates are the same as on the last day of last week.

Potatoes

There is no material change in the potato market, although there is some uneasiness in the general tone, causesd by the broken demand at certain intervals during the trading period. No receipts of old stock came to hand and only a few of the new varieties.

Salinas Burbanks ctl	2.50@2.75

Citrus Fruits.

The market for citrus fruits, while dull, gives some indications of bettering shortly.

Lemons	1.00@4.00
Navels	1.50@3.00
Seedlings	1.25@1.75
Grapefruit, seedless	1.75@3.00
Limes	4.50@5.00

Fresh Fruits.

In fresh fruits some grades are easier, while other stock is more secure in the demand and when taken in volume they average about evenly. The hot weather is quite favorable to the citrus fruit business, and while no change in the quoted rates occured, a more favorable tone was indicated by the steady trading. The watermelons and figs, which have been expected for several days past have not as yet arrived. There is but a small quantity of pears for sale, while cherry plums have been entirely eliminated. Nutmegs are in goodly abundance and were said to be of exceptionally good quality. The berry market is heavily stocked with supplies which are considered mostly first class. The raspberry market has a rather wide range of figures as the supplies at present consist of various degrees of quality.

Grain.

Trade conditions in the local wheat market showed no change yesterday. Prices remain steady and the transactions in spot stock continue limited to actual requirements only. Considerable stock is being received from the North, and this will doubtless increase a little later. Barley remains plentiful, with prices easy, though not quoted lower. The general inquiry is good, but there is not much doing in the export line.

Citrus Market

LOS ANGELES, June 18,1907.

The orange market still holds remarkable strength and insists upon closing the marketable season as it has carried all the way through with encouragement to the grower.

As will be seen by the following sample of auction sales,, even there strong conditions and good prices prevail.

Lemons are still more or less indifferent and playing a waiting game on the weather.

Shipments.

Shipments to date aggregate 23,513 cars, of which 2271 are lemons. Last year this date 23,015, of which 2743 were lemons.

NEW YORK, June 17.—The market is lower but there is good demand at prevailing prices. Weather hot. Thirty-eight carloads of oranges sold.

ALASKA SHIPMENT OF POULTRY.

The Coulson Poultry & Stock Food Co., Petulama, California, who are also exclusive breeders of White Minorcas and White Leghorns, are shipping this week 107 choice birds to the Yukon. They recently shipped several lots to the islands and a number of the poultry breeders in Oregon and Washington are breeding from their strain. The Coulson Co. took several prizes at the San Jose and Alhambra shows last fall.

It pays to have good birds.

It pays to show good birds.

It pays to advertise good birds.

And the Coulson Company know how to do all three of these paying things.

The season of special work in the dairy is always here. Are you ready?

Auction

100 Milk Cows
1 Holstein Bull

on H. H. Davis Ranch 2½ miles of DOWNEY

Take Southern Pacific train leaving Arcade depot at 8:30 a. m. to Vinvale, or take Whittier electric cars to Laguna; teams in waiting at either place until 9 a. m.

Friday, June 28th, 10 a. m.

Diet, Not Dope

In a speech before the Medical Institute in London, England, the other day the physician for King Edward called the attention of the assembled doctors to the fact that the use of drugs was being superseded by the use of proper food, air and exercise; and he was glad of it, believing the less drugs put into the system the better. With man so with chickens.

Use good diet. A. C. W. Foods, plenty of fresh water, a good yard to run in and you will have no trouble with poultry.

The National Irrigation Congress

The State Capitol at Sacramento, Where the Congress Meets

THE holding of the Fifteenth Irrigation Congress at Sacramento in September will make that city the center of attraction to many people from every State in the Union. The crowd anticipated has impelled the people of Sacramento to canvass the residence districts to secure accommodations for all, which the committee in charge assures us will be done and all will be comfortably housed.

Committees are at work planning a great program for the sessions as well as for drives, automobile trips, parades, etc., so that pleasure as well as profit is promised.

The widely varying conditions in California make the study of irrigation of particular and peculiar interest, accordingly a very widespread interest should be aroused in California and we should all join in making it one of the most successful and interesting meetings yet held. No pains will be spared to properly entertain visitors to the meeting, and every facility of travel in the way of rates, stop-over privileges, side trips, etc., will be available, and without doubt the attendance and interest in the fifteenth session of this National Congress, which bids fair to become an international one, will be in excess of any of its predecessors.

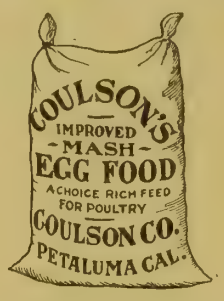
It may be of interest to have some information as to our State Capitol building which with its park of beautiful trees is the center of attraction of that city and much admired by its many visitors.

The building is 282 feet long and five stories high, including the basement. The corner stone was laid in 1860, and it was not completed until 1874. It is a splendidly built brick building, and is one of the most beautiful capitols in the United States. But it had too little room in it without being too small. Practically only three of the stories could be used; the basement being in effect a cellar, and the upper story only a fire trap attic. There was a scarcity of rooms for state offices, and none at all for committee rooms. This led the legislature of two years ago to appropriate $352,960 for a renovation of the capitol building. A year was lost in getting plans threshed out and contracts let. And the work has been going on for more than a year. The first work was to cut holes into the basement, make area walls for basement windows, take off the badly rotted wooden roof, and raise the walls, so as to make a full story of the upper story. These things have been done; the new steel roof is going on, and another year will see the work finished. The capitol has cost $2,600,000. It could not now be duplicated for $5,000,000 and probably not for $6,000,000, nor within five years of time. It can be enlarged at any time by building the wings at either end, as in the case of the capitol at Washington. The earthquake did not damage it.

Coulson's Improved Mash Egg Food

Takes Less Feed

Makes More Eggs



4 CENTS A MONTH
to feed a hen Coulson's IMPROVED Mash Egg Food Every Day Two eggs a month pays for the feed and when you get 18 to 20 eggs a month think of the money the hen earns for you

IF YOU WANT PLENTY OF EGGS THIS FALL AND WINTER when prices are high, you must lay your plans now. The hens must be given a strong feed which will enable them to get through the molt without loss of condition, and they will then quickly commence laying again.

First, see that your hens are healthy when they start to molt. At this time of the year, after a heavy laying season, they are apt not to be at their best, and a little of *Coulson's No. 3 Condition Powder* will put new life into them, and enable them to thoroughly digest and use the good food which they specially need.

At the same time, they must have the best food you can give them from the commencement of the molt. You will find *Coulson's Improved Mash Egg Food* is just what is required. It is strong in protein, due to the blood, meat, bone and oil cake meals which it contains.

Put Up in 90-lb. Sacks Directions in Each Sack

Your hens will not need to eat so much of the concentrated food to obtain the egg-making and feather-producing materials they need, thus saving their digestive organs and your pocket at the same time.

Coulson's Improved Mash Egg Food is therefore beneficial in two ways. Less feed is required and the hen gets just what she needs, with the result of a quicker molt and more eggs.

First cost is not everything, but even in this respect, COULSON'S IMPROVED MASH EGG FOOD shows to advantage. A 90-lb. sack will make a meal for 1250 hens. This is just over 2 lbs. a hen a month. Think how many eggs does it take to pay for this feed? In November, only 1 egg, and not more than 2 on the average.

We know what this feed will do by results on our own poultry ranch, as well as from testimonials from pleased customers all over California. What it does for others, it will do for you.

Give a trial order to your dealer; if he does not keep it, write to us, and we will either advise you where you can get it locally, or supply you direct.

The Greatness of the Golden State

An Article Written for Cultivator Readers by Clarence E. Edwards of the California Promotion Committee, in Which Attention is Attracted to Our Fertile Fields and Wonderful Resources

CALIFORNIA, the great State looking out through the Golden Gate upon the Orient and all the mysterious isles of the Western Sea, has but just passed the half century mark, but in that half century the wilderness has been tamed, homes have been made under skies as fair as those of famed Italy, and half a million families breathe an air equally as beatific. To the stranger to all things Californian, to one who forgets that the State's area is larger than all England and Scotland combined, it is difficult to give an adequate idea of what is here. When it is said that all New England, New York, Pennsylvania, Ohio and New Jersey, can be laid out in the giant area of mountain and plain of California, some idea can be had of the immense magnitude of the land which awaits the coming of the home-seeker.

California's Greatness.

It is difficult to talk about California without talking of big things for it is a big State, peopled with big men and women, and we take the big trees, big farms, big mountains, big valleys and big crops as a matter of natural sequence. To the stranger it is so vast, so varied that is is bewildering. Even the oldest inhabitant is unaware of all its splendid attributes and beautiful charms. No man has seen it all, and none can comprehend it all.

Far up on the top of the grim and rugged Sierras, where eternal snow lies silent under the calm of centuries, lies stored the power that means more for California's future greatness than all other forces combined. Here, where past ages look down from the fortress of Time, where Nature has been forging her gigantic storage battery against the day which should wrest its secret from the book of Fate, lies the great force which one day is to move all the machinery in the great State.

These melting snow banks furnish ever living waters, trickling down in constant streams all along the eight hundred miles of mountain chain which rims the eastern border of this wondrous land, and these streams hold within their confines latent energy sufficient to move the ponderous engines of the whole world. One little trout stream, with scarce sufficient water to float the toy boat of children at play, gives hydro-electric energy sufficient to send one of the great ocean grayhounds in faster time than ever was made. This little stream, confined in a steel tube nearly half a mile high, develops a power so great that were its force thrown against the big turbine which gathers power from Niagra Falls, it would crumble that machinery as if it were made of carboard.

These little streams are sending their energies by electric wire, over miles of hills and dale to cities and valleys of the Coast, furnishing the power which moves our street cars, our suburban trains, our mills and factories, giving light and heat in all the cities and towns from one end of the state to the other. Yet this great resource of cheap power is but in the infancy of development.

Oil Fields and Minerals.

California's oil fields are exceeded by but one other country on earth, and as development of this great resource progresses it bids fair soon to eclipse even the famous field of Baku, in Russia. Cheap fuel is now being supplied the greater portion of the civilized world, and with each succeeding month comes increased supply to meet the ever increasing demand. Combined with the cheap electric energy from mountain streams this is paving the way to make California the greatest manufacturing State in the Union, for here we have every raw material that is needed.

Water, the Source of California's Greatness

In Nature's gigantic storehouses in the hills lie every known commercial mineral product but waiting for man to dig it and transport it to where cheap natural fuel awaits to transmute it into all the varied articles called for in this, our modern day of civilization. Millions of acres of California's area are covered by the greatest virgin of forest within the borders of the Nation. Here is the newest of lumber cut from the oldest of trees. Redwood comes from the Sequoia, and the Sequoia comes from those past ages of earth when the mammoth, the cave bear and the three-toed horse roamed the dim aisles of the forest, hunted by prehistoric man. It is a tree knowing no home in other land than California, where it has withstood the cataclysms which have swept its cogeners from the face of the earth. Vast forests of pine and fir border this wonderful forest of Sequoia, forming a lumber supply that cannot be exhausted at the present rate of demolition in two hundred and fifty years.

Vast Fertile Fields.

In the great interior valley, five hundred miles

Cultivation, spraying, pruning, fertilizing are the four corner stones of orchard management. In which one did you fail the last season?

Deciduous Fruit Culture

BAGGING OF TABLE GRAPES.

THE Experiment Station Record gives under the above head the results of experiments made for a period of five years. The results of bagging grapes, when properly done, are extremely satisfactory.

At first, thin, transparent paper bags with the bottom removed and a V-shaped cut made in the center at the bottom were used. The results were not satisfactory as the grapes would scald during hot weather. Another style was used, the bottom being cut out and a cloth covering added over the bag. The bags had a fine copper wire encircling the bottom edge enabling it to be closed during wet or cold spells and opened again when warm. The upper part of the bag is reinforced with a pasteboard band which prevents the bags from coming in contact with the grapes. The bags were fastened to the supporting branch and not to the stems of the bunches. The arrangement formed a ball-shaped enclosure under which the grapes ripen. Over 600 bunches were treated in this way. The grapes were much larger than those in the more poorly ventilated bags.

Grapes bagged when in bloom did not drop so badly after blooming as those without bags; ripened ten days earlier and were larger.

Three different periods were selected for putting the bags over the grapes. Previous to flowering protects the bloom from cold, wet weather. Just after thinning gave the best results. Bagging just before maturity serves as protection against insects and helps to retain the bloom.

Bagging grapes is an operation which will never be done on a large scale in California, but the home collection of grapes in the city or even on the farm may be made much more valuable by this process. It eliminates the depredations of birds, gives larger and better grapes and extends the season over a longer period by treating only part of the vines in this manner. Ripening was hastened from 12 to 15 days. The process is described as being simple and inexpensive. This being the case and the fact that the grapes ripen two weeks earlier opens up a commercial possibility for the careful and painstaking horticulturist.

SUMMER PRUNING.

Now is the time when the over-methodically inclined fruit grower persuades himself to believe that he can benefit his tree by pinching back the ends of the branches and save heavy pruning in the winter. Don't do it. Anything that checks the growth of even the ends of the branches will check the growth of the entire tree. The size of the branches and the main stalk will not be so large at the end of the season as when the young growth is allowed to grow at will. It is the rapid circulation of sap that builds up the maximum amount of tissue (or wood) and that is what we all strive for in a young tree. That is what we plow, irrigate, cultivate and hope for. When the regular pruning time comes for deciduous trees, cut off the rank growth to your heart's content and you will not lose anything by it. It will only make a stronger growth, but don't go around and pinch off the fast-growing tips in the endeavor to make the tree grow symmetrical. If the bugs or worms performed that operation we would take on a lot of trouble. The young tree that gets out of shape during its summer growth will get into shape again when it gets down to a moderate yearly growth. It can be helped all that is necessary or desirable at the winter pruning time.

SUSCEPTIBILITY TO BLIGHT.

Pears are more susceptible to blight than apples, although some apples blight badly, particularly while young, says the Denver Field and Farm.

Then, again, many varieties of apples blight badly on the blossoms, even though no serious destruction to the tree occurs. The ordinary French pear stocks are, of course, seedlings, each one of which has its own individuality and different resistance to blight. The general average of French seedlings in blight resistance is low, that is, they are quite inclined to blight, particularly as many of them sprout badly.

A stock, therefore, which could be propagated by cuttings of known and tested resistance would be particularly desirable. We have this in the case of the Le Conte which is only fairly resistant to blight, but at least its resistance is known. It is propagated extensively by cuttings, as it roots quite readily in deep, sandy soils. Furthermore, these rooted cuttings are frequently budded and thus used as stocks. The Kieffer pear is also propagated in the same way, but is less commonly grown from cuttings, as it does not root so well as the Le Conte. When rooted it is rarely or never budded to other varieties in commercial nurseries. It might be a good idea to so utilize the Kieffer if it were not a little difficult to root as cuttings. It should certainly be a fine thing to use as stocks. In fact, it would be better to grow the Kieffer up to the second or third forking of the limbs and then top-work to Bartlett.

The Kieffer is not by any means wholly immune to pear blight, but it belongs to the most resistant. One of the few stocks available or already in use, of known resistance, is the Angiers quince which, of course, makes a dwarf pear. This, however, has been generally condemned for commercial planting but we have seen some excellent yard trees of Bartletts grown as dwarfs. These, however, were not originally Bartletts. They were Angouleme, or some other variety propagated on quince roots and afterwards top-worked to Bartlett.

MOTH TRAPS.

Much has been claimed for moth-traps as an aid to the fruit grower in ridding his orchard of insect pests, but Prof. W. F. Massey, of the Practical Farmer, discourages their use, saying:

"We tried, many years ago, the same arrangement that has of late been patented and extensively advertised as a trap for catching injurious insects. We found then, as almost every entomologist in the country has found, that the traps caught many more beneficial insects that it did harmful ones. At the University of Ontario the Haseltine moth-catcher was tested from June 7th to September 7th. The result was that, of the insects captured, nearly 75 per cent were of decidedly beneficial character, a considerable percentage of harmless ones and only a few harmful ones, with not a single codling moth, which the trap is especially advertised to catch. Prof. Lockhead remarks that as the maker of these traps boasts that he has sold 40,000 of them during the past season, if all of them were in operation during the season, there were probably forty million decidedly beneficial insects destroyed. The lantern moth catchers will not catch the codling moth, as has been demonstrated at every station in the country, and it will do far more harm than good. Better depend on spraying your trees, and then study insects so as to know friends from foes.

MEDIUM LOW-HEADED TREES.

I prefer trees medium low-headed, so as to have room to pick up dropped fruit. Then one can gather faster from the ground than on ladders, and I find that trees do not split and break off when heavily loaded with fruit, as they will rest on the ground or can be more easily propped than those with high tops. If they are too low the fruit does not appear to color as well as when off the ground a little distance.

The common practice in our locality is medium low-headed. I hardly think borers would do any more damage to low-headed trees than high. The flat-headed borers generally attack a tree that has some injury on it, sun-scald, rotten wood or something of that nature on the tree that is injured.

The fruit on medium low-headed trees is not damaged so much in wind storms unless it falls from the very top. As I have but little experience with high-headed trees, I cannot say which is easier to destroy caterpillars on, but since I can spray medium low trees with less difficulty, I should imagine they would be more readily destroyed on the medium low tree.—Iowa Farmer.

STIR THE SOIL.

The Cultivator recently spoke at length of the necessity of introducing air to the soil in order to allow the little beneficial bacteria to work their mission in increasing fertility. No matter how much fertilizer, expense may be incurred; unless the mechanical condition is right the elements cannot so arrange themselves as to be of value to the rootlets. Along this line Colman's Rural says: Depth and fertility being obtained, there are several other things to be considered in gardening. The soil must be worked frequently, beginning as soon after the sowing of the seeds as the young plants can be seen and saved. The frequent working of the soil not only continues it in good condition for the growing crop, but keeps ahead of the weeds.

whereby the strawberry may perpetuate its species. By means of seed and by means of runners. Restricting the efforts of the plants, put forth in this direction results in finer fruit. Some varieties of plants send out large numbers of runners while other varieties make but few.

Nature has provided two methods

Rake up all trash and burn and destroy many hibernating insects and plant diseases.

General Agriculture

USE OF POTASH.

A WELL-KNOWN agricultural journal discusses certain experiments in the use of potash salts upon the nature and quailty of barely. Inasmuch as there is a great tendency upon the Pacific Coast to change from the growth of wheat to barley, the results of these experiments in Germany will be of interest. This article may be summarized as follows:

Experiments were conducted to, determine whether it is advantageous on the more fertile soils to use Kainit and other potash salts in growing barley and to ascertain in what quantities and at what time the application should be made to be profitable.

In five tests with barley and wheat on fertile clay soils a general application of superphosphate and nitrate of soda, furnishing 220.5 pounds of phosphoric acid and 50.6 pounds of nitrogen per hectare, respectfully, was made and in addition 132 pounds of actual potash was applied. These soils range in calcium carbonate from 01.6 to 1.06 per cent. and in potash from 0.21 to 0.48 per cent. With every test the potash apparently increased the total yield, the increase amounting to 1214 pounds of grain and 1146 pounds of straw per acre. When potash was omitted the protein content of the grain increased and the starch content decreased.

A gravelly soil containing 12.40 per cent. of calcium carbonate and 0.13 per cent. of potash, producing potatoes and fertilized with barnyard manure the year before, received an application of 198 pounds of phosphoric acid, 33 pounds of nitrogen and 175 pounds of potash per acre. Applying the potassic fertilizer some time before sowing the barley proved beneficial and under these conditions Kainit was more effective. The increase in the yield of grain and straw apparently due to the potash was noteworthy.

It is pointed out that barley requires phosphoric acid, nitrogen and potash in a readily available form and in proper proportions, and that the quantities of potash given may be relatively small, if the preceeding crop was fertilized with barnyard manure; but that they should be correspondingly increased when two or three years have elapsed since the manure was applied. It is stated that barley responds best to the use of Kainit, but that on heavy soils the more concentrated potash salts are preferred.—Geo. Wright.

USE OF ALCOHOL IN FARM ENGINES.

In response to a widespread demand for information on the adaptability of alcohol as a fuel for use in internal-combustion engines used in farming operations, the office of Experiment Stations issues Bulletin No. 277. The office carried on a series of experiments with a two-fold object: (1) To determine what can be done with alcohol in existing engines and (2) to learn what changes in the mechanism of the engine are necessary to secure the highest efficiency in the use of alcohol as a fuel. The bulletin is a popular discussion of these experiments and of the mechanism and operation of gas engines in general with a short treatment of the comparative cost and relative adaptability of different fuels. The principal conclusions derived from the experiments are as follows:

"Any engine on the American market today, operating with gasoline or kerosene, can operate with alcohol fuel without any structual change whatever with proper manipulation.

"Alcohol contains approximately 0.6 of the heating value of gasoline, by weight, and in the Department's experiments a small engine required 1.8 times as much alcohol as gasoline per horse power hour. This corresponds very closely with the relative heating value of the fuels, indicating principally the same thermal efficiency with the two when vaporation is complete.

"The thermal efficiency of these engines can be improved when they are to be operated by alcohol, first, by altering the construction of the carbureter to acomplish complete vaporation and, second, by increasing the compression very materially.

"The exhaust from the alcohol engine is less likely to be offensive than the exhaust from a gasoline or kerosene engine, although there will be some odor, due to lubricating oil and imperfect combustion, if the engine is not skillfully operated.

"It requires no more skill to operate an alcohol engine than no intended for gasoline or kerosene.

"There seems to be no tendency for the interior of an alcohol engine to become sooty, as is the case with gasoline and kerosene.

"In most localities it is unlikely that alcohol power will be cheaper or as cheap as gasoline power for some time to come."

THE FARM DOG.

I belive the farm dog is as much help to the farmer's wife as to the farmer himself. Many men think there is not a place for a dog on the farm. This is true as he is generally treated. But if you have an intelligent animal he can be trained so that he will be helpful in many ways. The dog's place is primarily around the house. I do not believe he should go upon the road with a team. If he is useful he will not be in the field much of the time.

The Scotch collie is the ideal farm dog. He is intelligent and well adapted to the farm house. I have known well several of these dogs. We had one ourselves and our neighbor has one now. Both of these showed an extreme degree of intelligence. Our dog was more of a pet, although he knew in a moment when anything was wrong around the place. He never went away from home with a team, and he spent little of his time in the field. He watched the chicken yard closely, and whenever a fowl gave the warning that a hawk was in view he was up and ready to chase it away. Just as soon as he could catch sight of the bird he would begin running around under it and barking vigorously. Very few of our chickens were taken during his lifetime. If any of the stock got out of place because the fences were down or gates left open, he knew in a moment and did his best to get them back or inform us. He was very fond of the children and never showed any signs of snappishness. As a watch-dog the collie will be of great help. The farmer's wife is often left alone, both in the daytime and at night, and if she has such a guardian she feels safe.—Dairy Farmer.

A Safe Axe

Every Keen Kutter Axe is fastened to the helve by the Grellner Everlasting Lock Wedge (used only in Keen Kutter tools)—a simple device which once driven home in any tool unites head and handle so securely that only *fire* can separate them. Hence a

HARVESTING DOLLARS

The harvest of dollars is on in Southern Alberta, and the man who gets in during the next few months is the man who is going to reap his share of the harvest.

If you have been watching the trend of events in Western Canada you know that land has been gradually advancing there, and you know that the people who have gone there to make their homes on Alberta's fertile acres are making more money than they ever made before.

There is a better opportunity offered right now in Southern Alberta than has ever been offered there or anywhere else before.

On the great Canadian Pacific irrigated tract, comprising 3,000,000 acres of the best land in America, is to found the opportunity of a life time.

On this tract the farmer need never fear that his crops or live stock will suffer for water. Every farm has an irrigation ditch running thrcugh it, and the water is always ready to be turned on.

There is no better soil anywhere for raising Alfalfa, Sugar Beets, Wheat, Oats, Barley, Cattle, Horses, Sheep or Hogs.

This land is located near Calgary, which is a thriving Canadian city, growing by leaps and bounds. Large grain elevators are located in every town along the line of the Canadian Pacific, and one of the largest packing houses in Canada is running full blast in Calgary. Thus the farmer has the best of markets at his very door.

It is a fine trip through Alberta and Western Canada, and we are glad to have people come and see the country, because when they come they fall in love with it and stay right here. Send us your name and address and let us tell you how to make the trip at very small cost, and how to get a piece of this fertile land at a price so low it will surprise you, and on terms so easy that any man can own a farm.

MILK CANS ROB YOU

Look through a microscope at milk set to cream in pans or cans and you'll see how they rob you. You'll see the caseine—the cheese part—forming a spidery web all through the milk. You'll see this web growing thicker and thicker until it forms solid curd. How can you expect all the cream to rise through that? It can't. This

caseine web catches a third to half the cream. You stand that loss just as long as you use pans or cans for they haven't enough skimming force to take out all the cream. But, just the minute you commence using a Sharples Dairy Tubular Cream Separator, you stop that loss.

Sharples Dairy Tubular Cream Separators have 10,000 times more skimming force than pans or cans, and twice as much as any other separator. They get all the cream—get it quick—get it free from dirt and in the best condition for making Gilt Edge Butter. Caseine don't bother the Tubular. The Tubular is positively certain to greatly increase your dairy profits, so write at once for catalog I-260 and our valuable free book, "Business Dairying."

CALIFORNIA DAIRYING.

Continued from Last Week

THE high wages paid to the milkers makes it a matter of importance that cows should be profitable. A cow that milks ten pounds of milk is counted as one in the string of thirty the same as though she milked fifty pounds daily. It is more profitable to have the cows kept in a small field or a corral and to feed them on cut green food, than it is to have them roaming over a thousand acres of land to hunt their food. When allowed to roam over the country, they are apt to be gathered in by a cowboy, racing on his pony and yelling as he swings a long lariat over their backs; they run wildly and jamb through the gates to their hurt. This is not an imaginary picture but one that is happily disappearing. I saw it, however, only last evening as I came here on the train. It was a pitiful sight to see the poor, frightened cows trying to run.

Weed Out.

When I see the creameries dotting the State, creameries that pay their patron by the pound for butter fat, I know that this form of dairying is doomed. It does not require abstract reasoning to say ten cows; milk thirty days; returns so many dollars; divided by ten so much per cow, not enough to pay for the milking! A few cows are, therefore, discharged as unworthy servants.

The improved cows are increasing all the while for even the scrub dairyman admits that the pure breeds are desirable. As to care? That is improving rapidly. The human spirit is growing in California. Cows are well treated ,as a rule, while the money value of horses has brought about gentleness in their care and use.

An Experience.

The struggles of the early dairyman are little appreciated today. Fifteen years ago the cows that had any dairy blood or training were scarce; I bought the few I could find. Finally bought fifty-eight just from Arizona. They were cheap in price—$15 a head—but dear enough by the time they were educated. They had horns so long and sides so lean that if the horns had not been on to anchor them I believe they might have been in danger of sifting out through the slats of the car sides like sand.

We sent these cows to the lower ranch to be broken to milking. First of all their horns were clipped off and they were confined to a small corral and fed. They gradually became gentle, as they freshened the calves were removed and the cows milked. A chute long enough to hold ten cows was built, the cows driven into it from one end of a circular corral. Two heavy, movable bars were in front of each cow, two at the rear, two over her back and one under her stomach. She could not go forward or backward or lie down or jump over the top. A side slat was loosened and the milker sat down to milk; it was kick, plunge and bawl at first and only a little milk was secured. When ten cows were milked they were let out of the chute and another ten were milked, the process was repeated until the fifty-eight had been milked. One milking a day was all that was attempted. The calves were allowed to remain with the cows until eight hours before the next milking time for it took all day to milk the bunch. After six weeks twenty of these cows were well broken and could be milked when simply tied up. These were sent to the ranch and added to the herd. The remainder were milked in the chute the rest of the season. When ready to turn out as dry, only nine were refractory and were beefed. Forty-one proved to give milk enough to be profitable when well fed. The best cow of the lot made over four hundred pounds of butter one year; eleven went over three hundred and fifty. Twenty-one of them brought in nearly twenty dollars profit a year apiece; eleven cleared fifty dollars each while one made sixty dollars one year. This is what feeding did in grade stock.

Pure Breeds Better.

If those cows had been fifty-eight head of pure breds not one would have fallen under three hundred pounds of butter, some would have made it with their first calves, ten per cent would have readily made at maturity over 400 pounds a year on the same feed as the scrubs consumed. This is why pure bred cattle are profitable. They do not have to be culled out heavily. Where the means do not permit the purchase of thoroughbreds the grades of dairy stock are rapidly made and the gain from generation to generation pays well, for fully half the heifers take strongly to the best blood. The pure strain being prepotent for milk while the mixed strain is not strong for any one thing. This is the law of nature that unmixed inheritance is strongest. "We are strong when we ally ourselves with the laws of nature and weak when we disregard and disobey them."

Not only Breed but Feed.

The milk cow cannot produce in the hands of the poor feeder. Feed must supplement breed every time. New blood must be added from time to time to keep up the stamina of the herd; great care is needed in this or the step may be backward and cause a drop in the production. The breeders of registered stock are often tempted to breed too fine, forgetting that cows must have vitality, the cramped heart and lungs are not able to give a strong, good circulation to the blood. The idea that a cow is a milk-making machine is not correct in that it abuses nature, for there are never two individual cows exactly alike. Each inherits in a different way the qualities that come from ancestors. Each meet different surroundings and develops a little differently. Nature intended the cow to have milk enough to raise a calf. We have made her give quantities, often her own weight several times over in a year, or else in the beef cow we have wiped out the milking quality, so a

foster mother has to be used to raise the calves.

Don't Breed Too Fine.

After the cow had raised her calf nature's way was for her to rest and regain her vitality. Now we must feed the cow so that she does not expend useless energy in having to hunt for feed and we must make the surroundings healthy, peaceful and restful and do everything we can to encourage the cow to be vigorous and strong. Under the forced conditions of production a cow needs training from her birth fitting her for the future; she needs a protein diet and one that is bulky, so as to have a digestion that will be strong and not put on her back the fat from the feed. The sire at the head of the herd should not be used whose dam is poorly balanced cow. See also that she has a good udder, for that too is transmitted.

With weakened vitality the cows are easily chilled and then the tiny lurking bacilli of tuberculosis may take an active hold on the cow and their deadly work be well advanced before it is discovered. When we advance too rapidly toward greater production in either milk or butter fat we do it at the expense of strength, the types grow finer; when we introduce greater virility the cow grows coarser and the production of butter fat falls.

SHEEP NOTES.

Common powdered bluestone is the best remedy for navel ill.

It costs more to keep vermin-stricken sheep than clean, healthy sheep.

It is much better to use for breeding, animals of average size, smooth, and vigorous.

Teach the ram to lead; it makes him tractable and manageable.

A mixture of lard and turpentine is a good remedy for caked udder.

Good blood counts for little where good feeding is not in evidence.

There is a limit to the digestive powers of sheep; hence, feed carefully.

Buy a registered ram this year; the grade is not good enough for you.

Sheep are good "weeders," but they appreciate and pay for good pasture.

Don't forget that sheep will suffer thirst rather than drink out of filthy vessels.

Regulate the dose of medicine according to the age and constitution of the patient.

One dram of powdered ginger and one dram of laudanum is a splendid remedy for colic.

There are a few farms these days on which sheep can not be kept with a certainty of profit.

Success attends only the breeder who takes the utmost pains in selecting his breeding stock.

Don't market the sheep before they are marketable; whether breeding stock or butcher stock .

It is not policy to put a new purchase with the flock, at once as it might be the means of introducing disease.

You can't always judge a ram by his looks. Some of the best looking rams are often useless in the stud.

A cross-bred ram, no matter of how good conformation, can never be a proper substitute for a pure-bred.

Cream Separators, all sizes, all prices. O. J. Weber Co., 555-557 S. Los Angeles street, Los Angeles.

Weaning time is a trying time for both dam and offspring, hence they should receive extra care at that time.

Experienced sheperds say that sore teats and sore udders are often traceable to rations of a too nitrogenous nature.

Chalk and charcoal are useful remedies for lamb suffering from acidity and such like irregularities of the stomach.

It is always discouraging to be constantly raising inferior animals for which a less price must be taken than others receive for stock which cost no more to raise.

PLANS FOR NATIONAL DAIRY SHOW.

The Executive Committee has decided to locate the next meeting of the National Dairy Show (October 10 to 19) in the famous International Live Stock Exposition building, at the Union Stock Yards, Chicago.

The building is 600 by 310 feet, and there will be 30,000 square feet devoted to exhibits of all kinds of modern appliances and improved machinery used in the dairy, on the farm, in creameries, milk plants and ice cream factories, etc. Among the many interesting exhibits, there will be working dairies, sanitary milk plants and educational exhibits made by the U. S. Department of Agriculture and the National Association of Dairy Instructors and Investigators.

This building has an ampitheater that will comfortably seat 10,000 people. In full view of the ampitheater is an arena or show ring where the herds of thoroughbred dairy cows will be exhibited. The breeds represented will be Jerseys, Holsteins, Guernseys, Ayrshires and Brown Swiss, and there will be at least 500 of the record breakers.

There will be $10,000 awarded in cash prizes, medals, cups and diplomas to exhibitors of dairy cattle and makers of creamery and dairy butter and cheese. A very interesting part of the programme will be judging contests for dairy school students, who will compete with each other in judging dairy cattle and dairy products. Special prizes and medals and diplomas will be given to exhibitors of market milk and cream.

E. Sudendorf of Chicago is Secretary of the show.

The numerous applications for stalls and pens in the live stock department of the State Fair so early in the season, leads Secretary Filcher to believe that when the curtain rises on the opening day it will reveal the finest aggregation of blooded stock ever brought together in California. Quite a number of breeders have signified their intention of showing their stock this year who have never heretofore exhibited at the State Fair, including several from South of the Tehachapi. The services of Prof. W. L. Carlyle of Denver, who gave such eminent satisfaction in California a few years ago, have been secured to act as chief judge in this department and to lecture each day on the points of excellence on different breeds of animals.

A COW OF PARTS.

One of our exchanges advertises a cow for sale as follows: "Full-blooded cow for sale, giving milk, three tons of hay, a lot of chickens and several stoves."

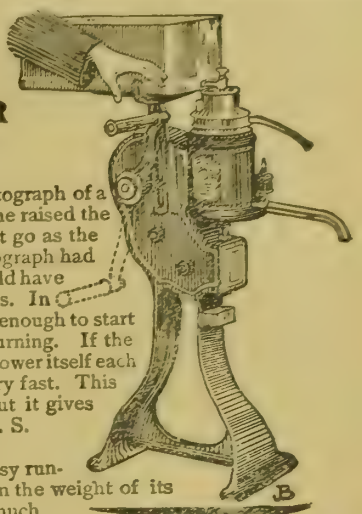
How the U.S. CREAM SEPARATOR Starts Itself



At the right is an exact copy of a photograph of a number 7 U. S. Cream Separator. Someone raised the crank to the height shown and had just let go as the photograph was taken. Now if another photograph had been taken about a minute later the crank would have been in the position shown by the dotted lines. In other words, the slight **weight** of the crank is enough to start the gears and bowl of the U. S. Separator turning. If the crank was raised enough times and allowed to lower itself each time it would get the gears and bowl going very fast. This would take some time so it is not practical, but it gives you an idea of how lightly and easily the U. S. Separator runs.

Other separators are **advertised** as "easy running" but the U. S. **is** easy running. When the weight of its crank will run a U. S. it certainly can't take much power on the part of the operator to do it.

We have n't room here to tell you more about the U. S. Separator, but if you want we'll be glad to mail you **free** a copy of our big, interesting, new separator catalogue. It tells **all** about the U. S. Just say, "Send catalogue number **C 20**". Write it on a postal if it's handiest, and address

The Ornamental Garden

SOME RAMBLES REAL AND FANCIFUL.

MORE than once the question has come to me from plant lovers: Does not the study of botany tend to tarnish the keenness of an artistic appreciation of flowers? Does not the mind pass on with a diminished notice to the mere points for classification? Certainly one might arrive at such a conclusion from the tedious reports of the study and experiments of cell development and structure which now seems to be engaging the attention of the botanists of the day that are most heard of. Their efforts are no doubt as worthy as they are energetic, but they represent a special line of research and only a small part of what is still botany to those who enjoyed the science as it was in the days of Asa Gray and Alphonso Wood. The modern method of teaching botany is a distinct failure unless it is desired merely to make specialists. The science of classifying plants is termed taxomony, and until very recently was the branch first presented to the learner who thereby at once acquired some knowledge of the plants he studied from the outward form and appearance of their different organs. Let no fear of a blunting of the artistic feeling prevent anyone from entering upon the study of botany at this portal. Can anything be less graceful or less beautiful for being more interesting? But it is not interest alone that we encounter at every step. First the unaided eye by reason of closer observation notes beauties hitherto undetected; then with a simple magnifiying glass, which should be as common as a pocket knife, a new world is presented—a charming fairy world of soft and bright and glowing colors and graceful wonderful designs unmatched by the most exquisite jewels. The eye that delighted in a mass of color and asked only that it be harmonious in its blending, now seeks grace and form and finds them where they did not exist before.

An extreme instance is that of a common dooryard weed heedlessly trodden upon with perhaps no motive at all. I refer to what is known as knot-weed or joint-weed, a rather friendly and not distressing little weed, which like the common plantain is said to follow the footsteps of the white man. Botanists know it as polygonum aviculare. Many people never see the flower on this plant, yet there are many on a single specimen, and under an ordinary lens they are not unlike tiny lilies. Those who know the smartweed will know what the flower is like, as that is a Polygonum also, but in the knotweed the flowers are almost hidden in the angles of the leaves.

A less marked instance is our mountain form of alfileria. Have you ever examined at all minutely this little wild geranium, or more correctly, storks-bill? Graceful, delicately cut leaves, pretty dainty petals, the column which bears the seeds being turned on its stem in such a way as to readily suggest the neck and head of a stork. California children all know this plant as "clocks," and their habit of sticking the seed in their clothing and watching the long, hairy tail slowly wind around like the hands of a clock, winding as it dries and unwinding as it is moistened, is an interesting experiment which demonstrates the manner in which the seed plants itself. This little plant has many beauties and were it not so common would undoubtedly be prized in garden collections.

It would be a pleasing but almost endless task to dilate on the many ways in which the intimate study of plants adds to their beauty and interest.

May Smiley Heights, while different is not less beautiful than April Smiley Heights. The glory of the Acacias is past, but the Deodars, Cypresses, Pines and Firs seem especially prepared to receive visitors. Their soft blue and gray greens give a peaceful soothing effect to the landscape. The Acacias have forgotten the fatigue of blooming and have the air of getting ready for the summer outing after the season.

Along the ridge at the southwest of Cañon Crest Park, the gaillardias are seen to their best advantage. When in sole possession and well but not over massed, they command admiration of their imperial colors and stateliness.

Spirea still pleases the eye. The classical myrtle, Myrtus Communis, is about to unfold its profusion of little white stars. The Hypericum or St. James Wort, a shrubby species, is displaying its flowers of a peculiarly rich yellow that seems somewhat different from all other yellows. The English Privet—the best of hedge plants, is displaying pyramidal panicles of white flowers looking very much like Spirea Japonica. Two yellow Brooms are noticeabe, both of which are occasionally confused with the Scotch Broom. The commonest one is probably Canariensis or the Canary Island Broom. The other, which is almost leafless and bears, large yellow and intensely fragrant flowers, is known as Spanish Broom (Sparium Junceum). A small shrub of this species has become established just below the top of the crest on the northern slope facing the San Timoteo Cañon. To the practised eye it is startling to see this blossom where all else is wild. It, however, blends well with the native flora, as the hillside is covered with the beautiful, golden, sunflower-like plant called Encelia farinosa. One of the handsome bottle brushes Callistemon rigidum is in full bloom and the display of variegated aloes is extremely interesting and striking.

One of the effects which is especially worthy of admiration is the varied and graceful sky-line produced by the tall gum trees.—Louis A. Greata in Redlands Citrograph.

A GOOD TIME TO HELP.

Mrs. W—— went shopping one afternoon, and little George, taking advantage of her absence, committed many misdeeds, says the Chicago Tribune, On being told later of his misbehavior she promised the little truant a whipping.

Evidently pondering over the punishment which was to visit his bad conduct, never once did the guilty boy raise his head during the entire supper, but when the meal was finished he immediately stole up to bed.

His mother walked softly behind. Kneeling at the bedside his little hands joined and the little face turned up, she heard the boy's prayer: "O God, mamma says you like little children. If you want to help a little boy now is a good time."

Both God and mamma heard the prayer, and George's request was granted.

TOO FUNNY.

"Mary," said a lady to her cook, "I must insist that you keep better hours, and that you have less company in the kitchen at night. Last night you kept me from sleeping because of the uproarious laughter of one of your women friends."

"Yis, mum, I know," was the reply; "but she couldn't help it. I was tellin' her how you tried to make cake one day."

The Vegetable Garden

LIMA BEANS.

In view of the fact that many early vegetables have not been much of a success this season a greater interest is likely to be manifested in those which will do their best in warm weather. Among these are Lima beans, and a writer in the American Cultivator gives a good account of the different varieties, saying:

In the south, Lima beans are among the more popular varieties, but in the north, many have regarded the season too short for the Lima to properly ripen. This was especially true before the introduction of the bush Limas, in 1890. True, in many favored sections the pole Lima would mature—but just as frequently it wouldn't.

With the introduction of Burpee's bush Lima, a bean fully the equal in every way of the large pole Lima was made available. In a rich soil the bush bean is quite prolific, needs no poling or support, and being in a circular bush form, is a pleasing sight. The bean of the Burpee bush Lima is a reproduction of the well-known pole Lima. The large pods contain three to five large beans.

Dreer's bush Lima requires several days more time to mature than Burpee's. The Dreer Lima has a shorter and thicker pod than Burpee's—in fact, is creased at the edges. The beans are thick, short and three or four closely packed in the pod. Dreer's Lima is inclined to be more spreading and less upright than the Burpee sort.

Henderson's bush Lima is a delicious little Lima, the smallest of them all. It is the very early Sieva, or butter bean, raised quite extensively in the south. The plants are very productive on rich soil. There are usually three or four beans in a pod. But few if any variety of beans surpasses Henderson's bush Lima as an entire or side dish. They are superb.

These three bush Lima beans, Burpee's, Dreer's and Henderson's are each similar, in being of upright bush form, require no poles, and are extremely easy of cultivation. But the beans of each variety, are of vastly different size.

While these bush Limas have been on the market but a few years, yet experts have continued to improve them. More recently, Burpee's Quarter Century strain of Burpee's bush Lima was brought out; also Dreer's Wonder strain of Burpee's bush Lima. The improvements aimed at in these strains were to keep the pods nearer the center of the plant, thus strengthening the bush, and also its prolificacy.

WATERCRESS.

This delicious little salad plant is a great appetizer and furnishes cuttings for table use very early in the season, says Coleman's Rural World. It should be more universally grown for home use than it now is. Those who are convenient to city markets have no trouble in disposing of all they can grow. The best place to grow this plant is in a spring or brook, for it must have plenty of water. As to the trouble which may ensue from sowing the seed where the spreading of the plants cannot be controlled a writer in an exchange thus cites his experience:

"We are often recommended to plant watercress in our brooks and ditches, but my experience is against this practice. I put a single spray of water cress in the muddy bank of a ditch running through the farm. In a few years the entire ditch, one-fourth of a mile long, was so entirely filled with the growth of watercress, which was sometimes two or three feet high in the ditch, as to block the ditch and prevent the water from flowing. Watercress has also taken possession of a running brook through another of our farms to such an extent as to be a serious pest. Several times a year we send men to clear out this ditch and brook in order to allow the water to flow more freely, but in a short space of time the watercress again takes possession. Our flocks of ducks delight to feed upon this watercress, but they have never been able to keep it within bounds and prevent its being a nuisance.

A WOMAN'S WAY IN THE GARDEN.

In June plant two hills of everbearing cucumbers for summer and fall and get a small dead tree, plant it deep in a barrow load of manure. Cover this pile with four inches of earth and plant around your tree Japanese climbing cucumbers. When the tendrils are long enough train them up the limbs of the tree and the result will be amusing to the eye, and fruit pleasing to the palate.

Plant sugar pie pumpkins in some bit of ground away from the cucumbers. This variety is the best ever known for pies. It is sweet, fine in flesh, small in size, and will last over winter until April. Last year I raised over four dozen. We sold some; gave some away and had our last pumpkin pie on April 9th.

Late tomatoes may yet be planted. If you have the earth well enriched and keep the ground well cultivated above the plants they will keep right on growing.

A stringless variety of snap-beans should be planted. These can be sowed every two weeks until the first week in August and this last sowing will be just ripe in time for the fall picking. The stringless variety makes the finest pickles. They are plump and tender.

The weeds are getting in good time now and unless checked and destroyed when small they will get beyond us. I find the wheel-hoe most excellent in destroying them. If the ground between rows is stirred up every day or so with the hoe, it will be an easy matter to keep the garden looking neat and attractive.

Hoe your beans when the leaves are dry, otherwise they will rust. While, again, no time is better for hoeing lettuce than after a shower of rain and a wheel-hoe run between the rows or hills of corn seems to make the plants grow before one's eyes.—Julie Adams in American Farm World.

A writer in the Garden Magazine says: "When you buy plants of tomatoes, egg plants or peppers at the corner grocery, the chances are that no name will be attached. You can never make any progress in gardening unless you start with named varieties. Even if the grocer offers named varieties you cannot be sure that they are truly named. And even if they are truly named, you have no assurance that the plants are the product of high-bred stock."

CONGO ROOFING

The time to be satisfied with your roofing is five years after you bought it. That's the test that Congo asks for. Durability is the only thing about a roofing that is really indispensable and Congo is full of it in the shape of high-grade weather-proof materials put together in the right way. Send for a free sample—and see for yourself. Cut open the sample—test it. If you can recognize what is good in a roofing, you will decide on Congo.

When writing advertisers, mention Cultivator

Does this stream of water look good to you?
It certainly does to the two men standing beside it. They are the President and Treasurer of the company to whom the plant belongs.
It is raising 40 inches of water from 250 feet below where they are standing. This water goes into a reservoir 18 feet above the pump through an 8-inch pipe-line about one-eighth mile long and you cannot see a pulsation in the discharge if you try. It has been doing this for over a year. There have been no repairs, not even new leathers, and it runs better, if such were possible, today than it did a year ago.
How many pump users can say this?
It shows conclusively that it pays to install good machinery.
We have done this for these people and we can do it for you if you give us a chance. Our catalog tells all about it.
Mail us a card asking for it today.

WESTERN WHOLESALE DRUG CO.
LOS ANGELES, CAL.

New System of Irrigation Flumes
Made of 2-inch iron tubing with holes any desired distance apart. Easy to lay, requires no repairing.
Cheaper Than Wood Flumes
Will last for years. Can furnish in any quantity. We also carry in stock several thousand feet of all sizes of standard pipe, and a general line of second-hand machinery. Engines, Pumps, Hoists, Pulleys, and Belting of all kinds.
R. Kelly Machinery Co., Cor. Mission Road and Macy St., Los Angeles, Cal.

California Horticulturally

A PROSPEROUS FRUIT SEASON.

IN SPITE of the early predictions to the effect that the deciduous fruit crop would be a total failure, the shipments so far have been unusually heavy and the prospects are that the total shipments for the season will foot up over 7000 cars. Among the more important crops this year are Bartlett pears which, in spite of the blight, are giving a good crop, much lighter of course than would have been had there been no blight. Apricots, too, are somewhat of a surprise and shipments of this fruit will be heavier than they were last season. Peaches are proving a very fair crop in most sections, but what pleases the growers most is the fact that prices for all classes of fruit are unprecedentedly high this year, and all those who have fruit for sale will have good bank accounts at the end of the season.

TOBACCO IN CALIFORNIA

Very many attempts have been made to grow tobacco in California but so far none of these attempts have been marked as commercially successful. Nearly every county has made a trial and so far none have succeeded in producing a marketable article. Why this should be so we cannot tell as it would certainly seem that in California with its great diversity of soils and climate, there should be some section in which good commercial tobacco can be grown at a profit. Mr. C. N. Ercaubrac, now of Santa Barbara, who has had as wide an experience in tobacco culture as anyone, having spent his whole life in the work, and in different tobacco sections, is willing to make a thorough and satisfactory trial of tobacco growing if he can be assured the necessary encouragement. Mr. Ercaubrack is an expert, in growing, curing and handling tobacco, and he expresses his belief that it can be successfully grown in California and made a source of great profit, if proper seed be sown and proper methods of cultivation followed. The trial is worth making for good tobacco land is worth more than any other kind.

TREATMENT FOR MORNING GLORY.

One of the worst pests in many of the orchards and fields of Northern California is the morning glory. In many cases it has taken possession of whole fields which have been abandoned to it, and even Chinamen have given it up. But even this pest can be eradicated with labor, constant and intelligent. All plants breathe through their leaves, and if these are constantly removed, or not allowed to grow, the plant will necessarily die. It is here that the remedy for morning glory is to be found. Do not allow it to come above the surface, and if it is so checked, it will in time give up the struggle for existence. The morning glory is perhaps the most persistent of all our vegetable pests, and should not be allowed to get a roothold in any field. Where it has appeared, however, it may be overcome by constant application of the weed cutter and every portion of it should be cut off below the ground. If this is done during the hot weather, and no water applied after cutting, until the tops have dried up a few applications will kill it out.

ENCOURAGING TO BEET GROWERS.

A very serious beet pest has been reported from Europe in the form of a nematode worm, a similar form to that which causes root knot on trees, and which is very destructive to them as many of our orchardists know to their sorrow. Dr. Earnest A. Beassey, pathologist in charge of the sub-tropical laboratory, U. S. Department of Agriculture at Miami, Florida, has been lately making a thorough investigation of the beet fields of the State with a view to discovering this or kindred pests, and he informed the writer that he has been unable to find any trace of it and is convinced that it does not exist in our beet fields which appear to be free from any pests of this nature.

DISTRIBUTING PARASITES.

The State Insectary for Beneficial Insects is now established in San Francisco, at the Ferry building, and beneficial insects are now being sent out on application from that point. The Comys fusca, the parasite of the Brown apricot scale has been very much in demand this season and large quantities of this insect have been sent to infested orchards. The parasite of the codling moth is now breeding out and all applications for this insect are being filled. The present is the height of the insect season and those who desire beneficial insects should secure them while they are plentiful.

THE STATE FAIR.

It is gratifying to record that more than usual interest is being taken in the State fair this year by our agricultural classes than in many years past. Mr. Filcher states that he will have representation from most of the counties and that the agricultural and horticultural interests will be fully represented.

MAKE READY FOR HARVEST.

It is money in the pocket of farmers to buy the best machines that can be had. Particularly is this true with machines that concern the hay and grain harvest. This naturally calls to mind the Champion, Deering, McCormick, Milwaukee, Osborne and Plano binders manufactured by the International Harvester Company. There are a half dozen machines from which to choose. You may be urged to buy one or another, according to the local agent you may happen to deal with.

They have all been on trial many years. All have been improved whereever improvement has been shown by experience to be possible. The International machines afford a good guarantee, perhaps the best guarantee to be had, that your busy harvest work will go on uninterruptedly, and that you will get all the grain, with little annoyance, and with the saving of all unnecessary work possible both for man and team.

International agents are to be found almost everywhere. That is an important consideration, particularly when you take into consideration the necessary repairs, which are matters that frequently require most urgent haste, and which the local dealers make it their business to look after.

If you are not fully prepared for the coming harvest, look up one or more of the local International agents in your town, get the catalogues, make a study of them and then talk to the agents about the machines you will need. The agents will have the machines on hand to speak for themselves, and they will be able to answer all your questions.

With the Citrus Growers

INFLUENCE OF CLIMATE ON SETTING OF ORANGES.

IN DISCUSSING the setting of this season's orange crop a few days ago, a Riverside grower advanced the theory that in sections where there is a constant or nearly constant wind blowing during the season of blooming the oranges do not set well. The chilly wind destroys their vitality to such an extent that only the more vigorous blossoms will set fruit. On this ground he had little faith in the future of orange growing in the desert regions now coming into cultivation. There are several experimental plantations on the Colorado desert but none of these are sufficiently far advanced to demonstrate bearing qualities.

The theory is not entirely substantiated, we think, from the fact that in former years there was no complaint on account of dropping but on the contrary there was much trouble from over-bearing and the demand for tree props was so great that all sorts of patent devices for propping over-loaded orange trees were sold by the hundreds of thousands. These have been in storage for a number of years but the records do not show that there is any appreciable change in the weather conditions then and now.

On the other hand, certain sections in the northern citrus belt where the weather conditions are ideal during the blooming period, the setting of young oranges has been heavy. This is perhaps only partial evidence and no doubt is no evidence at all, as the fact stated above that formerly in Southern California oranges set heavy while now the opposite is the case, except in some instances. In many of these exceptions, heavy fertilization has been continually practiced.

There is every indication that the bearing of the orange grove is under the control of the grower except in cases where there is some physical trouble with the trees or soil. These may and may not be overcome, but failure to set a crop of oranges cannot be laid entirely to wind, for there are hundreds of cases where full crops are grown almost continually and groves in the same vicinity are very seldom with a full crop. A great deal of the evidence seems to demonstrate that the orange crop is dependent on proper fertilization through the soil, and proper soil condition.

ORANGE TREES ON THE DESERT.

There are few "home orchards" being planted on the desert farms that have not a few orange and lemon trees, but many mistakes are being made in their culture and as a consequence there are few healthy looking trees. The soil is proverbially rich, and with this distinction it is deemed a waste of time by many to apply fertilizers. It may appear so with some trees but not with the orange and lemon. It has been our lot to inspect some twenty or more "home orchards" on the desert and in every case but three, the citrus trees were yellow and unhealthy. In these three cases stable manure had been applied and in one instance where the trees made the largest growth and were the richest green in color, manure had been placed in trenches around the trees.

In another instance nitrate of soda had been applied, one pound per tree, one year old. They were in excellent condition and were beginning to bear in the second year as were the stable manured trees.

The question of "bringing out" sickly orange trees in this region was the easiest thing we had to answer. The farmer in the desert country need not spend any money on nitrate of soda. Wherever barnyard manure has been used, the effect is most striking.

There is an unlimited supply of this material there as can be seen by the tens of thousands of heads of cattle and horses scattered over the country. There is considerable complaint in the Imperial valley about getting well rotted manure. It takes but a few hours for fresh manure to dry out and it dries as fast as it is piled up, and when cultivated into the soil it sometimes heats and is at best slow to become incorporated with the soil. This difficulty could be easily overcome by making a shallow pit into which water could be turned every few days. Owing to the absence of wells, windmills and tanks are almost unknown in the country, and all things must be below the level of the ditch to be wet.

The above facts indicate that the desert lands, while rich enough to produce large crops, are too deficient in nitrogen to nourish a citrus tree. They also serve as a striking demonstration that the orange tree is a heavy user of nitrogen. Our attention has never been called to a more positive demonstration.

THE PRODUCE MARKETS.—Los Angeles Market; San Francisco Market; New York Citrus Market; California Citrus Shipments, 678-679.

PROFIT IN PLANTED FOREST.

There are millions of acres of waste lands in California today, which could be made to produce annually large profit were they planted to forest trees for commercial purposes.

There are certain trees which pertain to certain localities but their nature, habits and longevity must be understood to make them a success. It is a waste of time and money to plant forest trees promiscuously without a knowledge of what classes will thrive in special localities. For instance, in California it has been found that white pine, yellow pine, sugar pine, mountain pine, Norway spruce, white elm, chestnut, cottonwood, live oak, willow, blue gums, and other eucalypts can all be grown and successfully in almost all parts of the state. But knowledge of their peculiar adaptability to climate, soil, and moisture is needed to insure success in a commercial way. This information may be secured by corresponding with the Forest Service at Washington, which is issuing, from time to time, circulars on the subject.

The time has come when forest tree planting may be gone into by intelligent owners of large tracts of waste land and handsome profits returned on the investment. It is a matter of common knowledge that our forests are rapidly disappearing. They have gone to satisfy the demands of commerce, and while the supply of lumber is diminishing, prices are constantly increasing.

To secure a continuous supply of timber it must be replaced by growth of the best species and the best form in the shortest possible time. This can be done by forest management; but the supply thus obtained must be supplemented very largely by timber grown in commercial plantations.

If the tracts of forest cut over each year were permitted to make a second growth, a future supply would be provided naturally, but this is not generally the case. The transformation of so large a percentage of forest land into fields and of nearly as much more, through reckless lumbering, into waste land must eventually reduce the wonderful fertility of the country, for no other natural agent is so active a soil builder as the forest. A pure water supply for large cities and towns and for the protection of irrigation reservoirs requires extensive planting along streams and canals and on watersheds.

The profits from growing timber are certain, and farsighted business men are recognizing the possibilites for conservative and highly profitable investment in forest plantations. More and more, railroads and other corporations and farmers throughout the country are establishing commercial plantations to supply the timber for their own needs or for commercial profit.

Financial profits in commercial forest planting can best be obtained by the selection of species which will produce the most valuable product in the least time. Many planters are not aware, however, that each kind of tree has a definite geographic and climatic range, beyond which it will not grow with sufficient vigor to justify its use for commercial planting. It is in selecting the proper trees for a given region that the prospective investor must use good judgment if the venture is to be successful. Mistakes are not only extremely costly, but they may not be found out for a number of years. Anyone who has observed the great number of plantations in the West which have not met the planter's expectations can readily appreciate the necessity for definite knowledge on this subject. To obtain this knowledge, direct correspondence with the Forest Service at Washington is recommended. Circulars on this subject will give all the data necessary and insure correct selection and proper care.

A HINT TO DAIRYMEN.

In Mrs. Sherman's article this week is an experience which may be of value to many dairymen now struggling on with very poor stock.

She at one time bought 58 head of wild Arizona cows. After a trying experience with them, 41 proved profitable. Twenty-one of the forty-one showed a net profit of $20 each, eleven cleared $50 each and one $60.

That may not have been an especially remarkable performance. But the point is here—How many of our farmers know whether eleven-fifty-eights of their cows clear fifty dollars or fifty cents each. More likely when fall comes there is, or there isn't enough money to pay taxes and interest and, pronto, "farming" pays or doesn't pay with no knowledge as to wherein it does or doesn't.

Nearly every dairy has its "boarders." Learn the fact then "beef" them. Nearly every orchard has its barren tree. Graft it or make it into wood. Many an irrigated field has its high spot where the water does not reach and loss of one or two crops of alfalfa or other crops on that spot results.

We suggest that "every farmer get busy with the details of business and know wherein the losses or profits come.

STREET IMPROVEMENTS.

Riverside has adopted a new city charter in which J. H. Reed, the veteran Tree Warden of that city, has recommended and the same has been incorporated into the charter, strict provisions for care of trees and streets, planting of trees and beautifying parks.

At an early day he promises the Cultivator an outline of the proposed improvements embraced in the new charter which may greatly assist other California towns struggling with the same propositions. It is doubtful if in the State there is another authority on street trees and improvements equal to Mr. Reed. For this reason his suggestions are of exceeding value.

SAN JACINTO RESERVATION OPEN.

Many letters are received by the Cultivator regarding the lands to be opened for inspection in July and for entry in August in the San Jacinto Forest Reserve. In the interest of those who are making inquiry we have been at some pains to investigate this matter and we are informed that the opening is not so attractive as many believe.

The lands are reported to be mostly barren rocky, hillsides on the northern and eastern slopes of the San Jacinto mountains and so sterile that they are considered of no value to the government for forestry purposes. If this be true they are of but little value for agricultural purposes.

OUGHT TO LIVE 100 YEARS.

Chief Chemist Wiley, of the Department of Agriculture at Washington, says it's a rank disgrace for any man in this country to die except from old age, and that all men should live to be 100 years old. The present generation, he declares, is going to live much longer than the one which came before, because it knows more about the laws of diet, hygiene and surgery. Mr. Wiley might also have added that our present system of outdoor exercise as practiced in our public schools is doing a great deal to lengthen the life of the present and future generation, because it is making stronger men and women of the boys and girls who are to be the future parents.

THE GREATNESS OF THE GOLDEN STATE

Continued from First Page

long and fifty miles wide, lie millions of acres of the most fertile land every kissed by the sun, and in all the nooks, valleys and vales of foothill and coast range, other millions of acres offer enticement to those seeking a place for home where is to be found the best there is on earth. To enumerate all that can be found for man's benefit in the hundred million acres of California were a task impossible of completion. Every industry followed by man is at its best here; every inducement that can be offered to man to make his home is found here. The climate is something more than a joy. It is a tangible, available asset and works in conjunction with man at all times. There comes no day when the skies and the air is not inviting to outdoor occupation. No stress of weather compels the farmer to provide against winter's cold or summer's heat.

A Warm Welcome.

From far toward the North, where the beautiful Siskiyous guard against cold to the southern line, where Mexico's barren sands mark the Anglo Saxon line, from the snows of the high Sierra to the equally white sands of the summer ocean, there is but one common thought—here is the best of everything. The orange grows to perfection clear to the State's northern line, and in the Southland, where semi-tropical verdure greets the travel worn visitor as he comes through San Bernardino's gateway, all Nature seems to bid welcome to those whose lives have been spent in lands where life has been a constant struggle for existence. No fruit grown in semi-tropical or temperate zone is there which cannot be found in its highest perfection in California, and one can never tell by the fruit on the table or the flowers in the yard whether it be January or June.

When it is said that California has a mean annual temperature of 62 degrees, little or nothing is conveyed to the mind of the true climatic condition of this wonderful state. California's climate should be written in flowers instead of figures.

Not By the Calendar.

Just when to plant and when to harvest in California is not regulated, as in Eastern States, by the calendar. Here planting and harvesting goes on continuously. With isothermal lines running north and south instead of east and west, with soil of the richest and with land sufficient to supply homes for millions California, today, offers the greatest opportunities of any section on the globe, for the homeseeker and the investor. It is a State where all may come and where all may find room and advantages unequaled in other land.

News of Country Life in the Golden West

Southern California

AGRICULTURE.

Covina is already planning for a chrysanthemum show this fall.

A large development of irrigation water is under way in Ventura county.

A grass fire, started near Banning, destroyed large quantities of standing grain.

The Southern Pacific people are at work on a model ranch near Imperial.

Coachella Valley hopes for the establishing of a plant for testing silk culture.

Riverside Creamery at Arlington Heights now puts up 22,000 pounds of butter a month.

Little Mountain back of San Bernardino was severely scorched by brush fire last week.

Again officials are surveying and studying the flow of water in the delta of the Colorado River.

Large shipments of thoroughbred stock were received at the Hollenbeck ranch near Covina last week.

Twenty-one carloads of cattle fresh from Arizona ranges were turned into Imperial valley to "finish off" last week.

The Patterson ranch at Oxnard is installing large quantities of wood pipe from the National Wood Pipe Co. of Los Angeles.

One of the large products from the desert country near Indio is mesquite wood of which thousands of cords are being shipped.

The "west side" potato growers near Anaheim are counting on big returns for their potatoes, some of which have been sold at two cents per pound.

The weather bureau is to establish an observing station at Brawley for the purpose of studying the climate and weather condition of Imperial valley.

Imperial Standard says methods of farming in that section have vastly improved from the primitive methods in vogue when the valley was first settled.

Big six-mule teams hauling wagon and trailer well loaded with grain lined up along the Riverside Railroad tracks from the Moreno section is a daily sight.

The Colonization Co. which is booming the Yucaipe valley is planning for a model farm where it is expected to give a thorough test of the "dry farming" plan.

Pomona Farmers' Club, with the other clubs affiliating with it, is planning for a great institute under the leadership of Mr. Neff on Friday and Saturday of this week.

A company has purchased the Foster ranch near San Juan, Capistrano, a tract which comprised 10,500 acres; it will be sub-divided, rented, or sold for small bean ranches.

The Arrowhead Reservoir & Power Co. are floating an issue of over $6,500,000 bonds to secure funds for completion of an immense power and irrigation plant for San Bernardino county.

A farmer of Santa Ana whose son was killed by contact with electric wires in a pumping plant alleged to have been improperly insulated by the Edison Electric Co., has begun suit for $10,500 damage.

HORTICULTURE.

Coachella valley orange groves have fruited one-half size already.

Already the output of oranges in Southern California is greater than that of last year.

Already the press of Southern California are reporting disastrous fires on the water sheds.

First Muscats were shipped from Imperial last week and commanded ten cents per pound.

The growing in a large way of Smyrna figs is under contemplation for Imperial valley.

One rancher near Indio claims to have harvested over $1500 worth of tomatoes from one acre.

Imperial valley is surely a warm one, for the Standard of that place says 109 in the shade just suits them.

A new packing house for handling oranges of the Bloomington district is to be erected in time for the next crop.

The packing houses of Santa Ana have finished the navel, seedlings and sweets and now have but few Valencias.

State Forester Charleton has appointed forest rangers to work in conjunction with the regular forest reserve rangers.

Warning is being published by the State Forester to campers to be careful in permitting camp fires to do damage during this dry season.

Supervisors of many counties in Southern California are passing quarantine regulations against Yuba county on account of the White Fly.

A whirlwind at Redlands last week made a lot of trouble with the apricot dryers by picking up trays of dry 'cots and scattering them in all directions.

The Covina Argus says that heavy pruning out of the center of Valencia orange trees has resulted in an immense crop in one of the Valencia orchards there.

With few exceptions, the apricot crop at Hemet was harvested by the last of the month. Many found their crops much larger and the fruit weighing heavier than they expected.

The La Mesa Packing Co., of Riverside, have elected the following directors: L. C. Waite, C. F. Marcy, S. H. Herrick, J. H. Reed, M. L. Colemen, P. D. Cover, L. H. Briggs, A. Habaerlin and J. E. Brown.

Olives will be a big crop this year at Hemet. It is said that hand-picked olives will bring from $150 to $200 per ton this year. Many olive trees were set here this spring and many more will be set next year.

A practical test has been made on the pre-cooling plant which was erected by the Santa Fe at San Bernardino, and so far as can be predicted, will be a complete success. It is claimed this plant will save $30 per car over icing.

Citizens of Santa Ana have begun suit against the Cutting Packing Co. and the California Fruit Canners' trust for the return of $4700 and real estate given the companies to encourage them to establish a cannery which was afterwards closed when the cannery was absorbed by the trust.

Northern California

AGRICULTURE.

Good hay crop prevails in most of the Sierra Valleys.

Luther Burbank has been offered $10,000 for his spineless cactus.

Petaluma has one incubator plant which claims to turn out 100,000 chickens a month.

The farmers near Corning are complaining of the inefficiency and trickery of the Jap laborers.

The bulk of the peach crop at Sutter county has been contracted for by canners at $70 per ton.

A meeting of the creamery men of Fresno, Kings and Tulare counties was held recently at Visalia.

Cottonwood, in Shasta county, is shipping large numbers of beef cattle to the San Francisco market.

Lindsay's citrus shipments, since January 1st, almost entirely Valencia oranges, aggregate 190 cars.

Tulare Register says that dairymen are in the line to make scads of money from the present indications.

Sutter county Chamber of Commerce have taken steps to make a fine exhibit at the coming State Fair.

Every hunter in the State must show his license after July 1st. See the County Clerk and get your permit.

Twenty-three cents for butter at the Merced creamery has been turned over to its patrons for the May output.

W. W. Mackie, an expert of the Department of Agriculture is making tests of soils near Woodland, Yolo county.

Several square miles of standing grain were burned near Delano last week. Said to be the biggest fire in that section in years.

Marysville Dairy Co. is planning for the building of a large barn 200x 70 feet, which will provide storage for 500 tons of hay.

Levee District No. 9, near Yuba City, has let a contract for improving of the levees, calling for moving about 200,000 cubic yards of dirt.

Papers over the North generally unite in claiming but little damage from the recent rains which it was feared would ruin much of the hay.

The annual creamery picnic of the Gridley Cannery held by the people of that place was a complete success, nearly 7000 people being present.

Redding is having a turn with grasshoppers which threaten great damage in Shasta county. Efforts are being made to wipe out the pest.

A $1,000,000 corporation has been formed at Turlock for the purchase of land to sub-divide into small ranches, also to engage in ranching for itself.

A serious foothill fire near Visalia destroyed hay presses and 240 tons of hay and much other property last week. Nearly sixteen square miles were swept by the flames.

The "west side" of the San Joaquin valley reports a fine condition of the grain fields, especially in Stanislaus and Merced county. Grain which a couple of weeks ago it was feared would give a very light crop, has been so favored by the weather that five to eight sacks per acre are promised.

HORTICULTURE.

Phillips' clings are selling at Visalia at $75 per ton.

Kuhn ranch near Visalia has been sold to the California Fruit Canners' Association.

Apricots are generally conceded to be well worth twenty-five cents per dry pound.

The Turlock Cantaloupe and Melon Association is about to build a 50x-150 packing house.

Plans are progressing for a new creamery which is about to be established at Vacaville.

Colusa county is planning to pull down the big prize offered for the best county exhibit.

The President has signed a proclamation making a National Forest Reserve in Inyo county.

Vacaville Reporter says that the prune men are the luckiest this year, with prices still soaring.

Fresno Republican reports the selling of 400 tons of green cling peaches to canners for $65 and $70 per ton.

Dinuba has a clean-up day with special attack along the line of fox tail and other obnoxious weeds along the roadside.

Oroville orange growers are on guard watching for any possible entry of the White Fly from Marysville, only a few miles away.

Committee in charge of the Tulare county citrus fair, report progress with a good fund already in hand as a starter for a successful show.

Secretary Filcher reports more promise of a genuine agricultural fair with more farmers falling in line with exhibits than for many years.

The citizens of "Tokay Town," which has become a synonym for Lodi, are planning for a carnival to be held during the State Fair week.

The people of Marysville are showing that they have the best interests of the State at heart by taking up all the orange and other plants infested by the White Fly.

The Anderson fruit belt will yield 5000 tons of prunes this season. This will be a record crop and from present appearances the prices will be a record price.

The Watsonville Pajaronian says that it seems probable that there will be strong competition for the apples produced in that section. This means money for Watsonville people who are apple growers.

The Porterville Enterprise says that a large part of the new colonies have been established near that section within the past year. This means prosperity for the Tulare county citrus interests.

An investigation amongst the orange trees of Sutter county develops the fact that no White Fly has infested them. Sutter county is across the river from Marysville which is so badly infested.

A peculiar pest which has not been named yet has appeared in the vineyards near Fresno, especially in the Wahtoke vineyard. The pest is an immense worm sometimes four inches in length which entirely defoliates the vines. It is controlled by laborers going into the field and picking off the vines and hauling away.

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER.

Used by all largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Haphazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultry men who have used these machines have supreme confidence in their ability to hatch and breed. Hence their ever increasing popularity. Winners of the Gold Medal at the St. Louis Worlds Fair for the greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1904.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any way you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A. Filcher, Commissioner.

And Now Comes New Reward for Merit

Read the following telegram received from the Lewis & Clark Exposition at Portland.
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Profit in the Poultry Yard

We solicit short articles of a practiced nature from the fancier and utility breeder, giving their experiences with poultry. All inquiries pertaining to feed, management, disease and its prevention, will be answered through these columns.

WARM WEATHER WORK.

With the approaching warm days the work in the poultry yard must be kept up if we wish to have our flocks in the best condition this fall and winter. All of us know how easy it is to let up on our work and we also know that our flocks will suffer more during the hot weather if neglected than they will at any other time of year.

See to the Youngsters.

By this time our young stock will be getting to a size where it will be necessary to remove them from the coops and put either in the colony houses or if we are not fortunate enough to have colony houses, put them in the regular poultry house. The latter of course is a bad thing to do, and if there is no other way we must take care to see that they don't crowd, if they do the house will get as hot as a bake-oven. We have seen chicks sweat at night until in the morning they looked as though they had been out in a rain, the feathers were still wet. After a night spent in this bake-oven they are weak and when the cool morning air strikes them or they get out in the dew, they are easily chilled and the first thing we know we have a sick flock.

It is also a mistake to crowd your old stock. Better thin them out, than try to put too many in one house. Fowls need more roosting space in summer than in winter.

What Shall We Feed?

The food is another consideration for both young and matured stock. We should feed such food as will produce bone and muscle, and avoid articles of diet that are of a heating nature. Corn should be left out of the ration entirely as it is too fattening and heating.

Make it a point to feed as much green food and vegetables as possible. If you can't arrange a run of grass of some kind, sow a small corner of each yard, say six feet square. Cover it with two-inch wire netting tacked to a frame and about three or four inches above the ground. As the grass comes through this the birds can pick the tops off and the netting will keep them from killing it by scratching or eating too close. You will be surprised how much green food you can get from a plot of this kind if it is well watered.

Keep the Houses in Condition.

If you have not already whitewashed your houses, do so at once. It makes them look cooler and certainly a great deal cleaner besides. It will keep down the lice and mites. If we have dirt floors remove several inches of the earth floor and fill it up with nice clean soil, it will help keep down the disagreeable odors; provide a scratching and dusting place. If you have dropping boards (all should have) clean them at least twice a week and sprinkle either ashes or air-slacked lime on them.

Provide a bin for droppings and when houses are cleaned put them into it, to either use or sell for fertilizer, taking care to have them as free from lime and ashes as possible. It is a good plan to keep the droppings damp, for practical tests prove that poultry manure loses more than 50 per cent of its fertility when allowed to dry, but if kept damp it is one of the best.

It will be necessary to open your houses earlier summer mornings, so the birds may get out as soon as it is light as they enjoy hunting for the bugs and worms. Be sure to have the houses well ventilated and keep the nests clean with fresh straw. Make them as inviting as possible, and you will be repaid for your trouble with nice, fresh eggs.

Breeding Yards.

We always think it best to keep one or two yards mated all the time as there is always some that want eggs for sitting. But if we only want eggs for home use, or market we would not allow a male bird in the pen as you will get just as many eggs, and they will keep better. The male birds that you desire to keep for another reason should be taken away from the hens, and placed in a separate run and fed extra well. They will come through the moult earlier and will be in a better condition to put back in the breeding yards in the fall or winter.

Range.

Give the youngsters all the range possible. It will help to develop muscle and bone. We would rather keep the mature stock yarded and give the chicks free range, we believe the old stock will be just as well off and certainly not so many eggs will be lost. Hens on free range will hide their nests, and often when we find them the eggs are not strictly fresh to say the least.

AROUND THE YARDS.

Keep the coops clean, and watch for mites.

* * *

Brains mixed with chick feed give best results.

* * *

Hard work is the correct definition for good luck.

* * *

Separate the cockerels and pullets as soon as possible, both will do better.

* * *

It takes grit for poultry, and this warm weather, we often need a little ourselves.

* * *

Anybody can start in the poultry business, but it takes a worker to make it a success.

* * *

Turkeys and chickens cannot be raised together on the same feed, especially if you feed a diet of corn or cornmeal.

* * *

Dust the chicks as soon as you remove them from the nest. To kill head lice grease the chick's heads with a little lard.

* * *

It is not necessary to have a pool for young ducks to swim in, but have the drinking vessel deep enough for them to get their bills well under water.

* * *

Don't feed chicks for twenty-four to thirty-six hours, but give water as soon as removed from the nests, keep coarse sand or grit before them all the time.

* * *

After they are once well started, goslings grow very rapidly and if well

cared for until they are well feathered they can be turned into a pasture and will look out for themselves. They are great foragers and eat great quantities of grass and other green stuff.

* * *

Canker.

My hens (S. C. White Leghorns) have a yellow, cheesy growth sometimes in throat; sometimes in windpipe or in roof of mouth. It appears not to be roup (diphtheria.) Sometimes the eyes are swollen and slight discharge from nostrils, but think it is water from the sore eyes; little or no odor. Hens fat (generally.) Sometimes find them choked to death—windpipe full and no other appearance of sickness. Notice them gaping at times. Hens have ten acres range in orange orchard. Plenty fresh water—have used bluestone since they are sick. Have begun treatment you prescribed for little chicks with canker sore mouth: sulpho-carbolate of zinc and peroxide hydrogen. Is that right? Canker seems to eat throat out at times.—Mrs. M. M.

You have serious trouble and you should be very careful to keep it from spreading. Separate your sick fowls from well ones and use a good roup cure. You can get same at any of the poultry houses advertised in the Cultivator. For those having canker, clean canker out of throat with a swab. Then take a stiff feather and apply Germazone well; this done once a day for two or three days will generally cure canker. Put Germazone in drinking water about one part to ten of water. Bathe eyes of afflicted fowls with one part water to one part Germazone. The bluestone you are using is also good. Find cause of trouble if possible and remove same. Are your birds roosting in a draft? Are you very careful as to cleanliness?

* * *

Mites on the Brooder.

In starting poultry raising on new place if everything is new and chicks hatched in incubator and no fowls bought would hens ever get lice or mites? Are ducks troubled with lice or mites?—F. G.

For some unknown reason poultry will be troubled with lice and mites. Even though they are hatched in an incubator and put in coops that have never had chicks or fowls in. One of the best theories we ever heard was that birds carry vermin. We know that English sparrows and pigeons will spread vermin. Ducks are never troubled with lice nor mites.

MARY HAD A LITTLE—!

Mary had a little hen
Upon the little farm,
Against the wolf behind the door
It proved to be a charm.

Each day it laid a little egg,
Which Mary sold at town,
And thus she bought her groceries,
And now and then a gown.

The years passed, and Mary paid
The little mortgage due,
And sent her girl to boarding school,
Her boy to college, too.

She has a nest egg in the bank,
And even keeps a cook,
And everything about her has
A thrifty, well-kept look.

She says to those who daily fail
With needle, brush and pen:
"If you would do as well as I,
Just keep a little hen."
—Daisy Wright Field in Rural Magazine.

Young folks tell what they do, old ones what they have done, and fools that they intend to do.

The sure mode of being deceived is to believe ourselves to be more cunning than others.

CULLING THE FLOCKS FOR SUMMER LAYERS.

We take the following from the Ohio Farmer as it covers the field about as thoroughly as any we have seen:

"As the spring egg season begins to wane and we are pretty nearly over with the hatching and brooding season, we begin to look forward to the flock that we must depend upon to produce eggs during the summer season. We find it very profitable to keep a good-sized flock of laying hens about the farmyard during the winter and spring laying season, but in order to give the increased flocks of growing chicks better facilities for range, it is best policy to cut down the laying flock, and get a better growth from the spring-hatched cockerels and pullets.

"Each season, at the waning of the laying period, we cull over our flocks, and discard those which we are aware will not be profitable for us to keep as egg producers during the heated summer season. The hens that have been the most profitable as winter layers and brooders in the spring hatching season are the early-hatched pullets from the previous year, and the two-year-old hens that were in prime condition at time of selection. These are the hens that at the present time constitute our flock, and at the closing of the hatching season we find them divided into several grades.

Kill Off the Fat Ones.

"Among this flock will be found a number of two-year-old hens that have become over-fat from high feeding for egg production, and as warmer weather advances they become still more so, and drone about lazily and will not produce eggs during the season to warrant their keeping until the autumn markets. Hence while spring markets are brisk, and such stock in good demand, these hens are culled, and placed upon the market. Indeed we keep over but very few hens of this age unless they have exceptionally good markings and promise a good constitution to carry them through for the production of eggs for hatching the following season.

"A few of the early-hatched pullets are also discarded for the same reason.

"Many of our hens become very fat while upon the nest, brooding, and rather than risk chances of reducing them and getting them back to a good laying condition we let them go upon the market while fat. Therefore, when our flock is properly culled and placed back in the farmyard we have endeavored to not only make of it a respectable looking flock, but as well a profitable laying flock.

Summer Layers.

"Then, in this summer laying flock we have an invaluable acquisition in the way of the late-hatched pullets from the previous season. These pullets have been carefully fostered during the winter season, not with the expectation of even early spring eggs. Indeed they are not laying yet at this date, but when July and August eggs are scarce upon the farm they will be furnishing nice fresh eggs. They appear to fill in a niche in the laying season that no other fowl can quite reach. The hatching period is Nature's rest of the laying hen, and if she be kept in proper condition during this time, with the right feeding and necessary condimental foods, she will be in good condition to commence laying again and will be paying her way quite soon.

"It is a mistake for the poultry keeper to attempt to keep too large a flock of hens during the summer season, as well as to over-crowd his houses in the winter. The farm range is free so far as it goes, but when it becomes over-crowded with fowls the profits must be reduced, and the best method is to curtail a portion of the flock before the profits are seriously affected.

Feed Them.

"A flock of hens should not be expected, even upon the largest ranges about the farm-yard, to subsist upon what they may pick up, for they will be found overstepping their privileges and doing damage to growing crops that otherwise would not result if they were given a ration of grain each day. Our flock gets the same care during the summer season that they get in winter, and we know that this extra care brings us in more eggs than to balance the extra added expense. Besides we need not dog our hens from the fields where they are damaging the crops from aggravated starvation. Feed the summer layers well and they will help feed their owner.

Water Them.

"Many flocks of fowls suffer immeasurably during the heated season from lack of water. They cannot be expected to furnish an abundance of eggs without water. Hens drink an abundance of water when kept where they can get it. At our place we have securely placed within the shade of a farmyard building a sixty-gallon barrel upon the side near the bottom of which we have placed an ordinary drinking fountain, such as is sold at all hardware stores, and used for the watering of swine. This attachment works automatically and the barrel is pumped full of water when necessary with the farm wind-pump, and it is safe to say that our fowls do not suffer from want of water at any time, even though the season be pressing and busy.

"Ordinary poultry fountains are good for their purpose, but where a large flock of fowls is dependent upon them for water, and the season is busy, the housewife too often finds them empty and the fowls starving for water. It is amazing what a quantity of water a bunch of fowls will consume if they have access to it, and they should have a plentiful supply, especially those that are being depended upon for the production of eggs."

DUCKS ON THE FARM.

No one can make so much money growing a limited number of ducks as the farmer. His business usually confines him pretty closely to the farm yet gives him a little spare time in winter and early spring which he might profitably spend raising four hundred young ducks, which could be sold at a few hundred ducks each season.

From a flock of forty good breeding ducks and eight drakes there need be no difficulty in raising four hundred young ducks which could be sold at an average price of four shillings per head. That means that they would produce more in four months than many farmers produce in a year from a small herd of cows and more than they receive for the sheep and swine they sell.

The equipment required is not expensive. A house thirty feet long by twelve wide, with a shed roof high enough to give head room to the caretaker, will accommodate forty eight birds, equally divided into two flocks.

It costs money to change your mind when you get the wrong roof on your house.

When writing advertisers, mention Cultivator

THE GUINEA AS A PROFITABLE FOWL.

With the gradual disappearance of natural game birds, there is growing up a demand in the cities for a domestic bird which has all the qualities of the game bird in color and texture of the flesh and the game flavor that epicures so much delight in. We refer to the guinea fowl, which has heretofore been kept more as an odd bird than because there was any particular profit in breeding it.

Let them Alone.

The Guinea, as we know it, is but one of many varieties, all of which originally came from Africa. The Ancient Romans were acquainted with the guinea fowl, but there is good reason for thinking that the guinea fowl of old Rome was one of the species found in Eastern Africa, rather than the native of the West Coast, which is found in large numbers in its native country, identical in shape and color with the guinea of our farm yards.

Guineas are fowls that do best when treated on the let-alone principle. They have a natural inclination to wander in the fields and seek their own food. If given a wide range, such as they can have on a farm, they care little for the feeds of domestication, wandering forth early and staying abroad late during all of the year when they can find seeds, green stuffs and insects to eat.

In mating guineas, not more than two hens should be allowed for one cock, although occasionally a cock will mate with more than this number. In their natural state they mate in pairs, but under domestication they have broken away from the original plan and accept more than one mate.

It requires from twenty-six to twenty-eight days to hatch guinea eggs, and it is best to hatch them under common hens.

Not very Tame.

When they are first hatched they are as wild as quail and will run away and hide, and finally become lost if they are not confined in a pen in which they cannot find a hole out of which they can creep, and they will find the hole if it is there. A pen made of foot-wide board will keep them long enough so they will become accustomed to the mother hen. Once they get acquainted with their foster mother and learn her language, they are very affectionate and will talk to her as they follow her about, never leaving her day or night. Indeed, they stay with the hens all the season and even through the winter.

Guineas are quite prolific layers, hiding their nests in the fields as does a turkey, unless they have been accustomed to sleeping in a house. If hatched with hens they do not have such wild dispositions and frequently lay in the nests provided for hens, until about the time when they become broody, when they will steal away to lay a clutch of eggs to hatch.

The young are quite tender for a few days and should be fed little and very often at first. In a short time they become hardy and after that will endure any kind of weather that may come, even to sleeping out of doors in the coldest weather.

The eggs are small but of good flavor, but there is no market demand for them and, except for home consumption or for use in hatching, they are not valuable.

Not Good Mothers.

Guinea hens are not good mothers. It must be a very favorable season in which a guinea hen will raise more than a few of the young she hatches. As a rule, they wander about through damp grass until the young are mostly lost.

Have that Gamey Flavor.

As remarked above these birds are coming more into demand all the time from city consumers, who are beginning to appreciate their tender palatable flesh, which hardly anyone can distinguish from grouse or pheasant flesh. It is a fact that in the larger cities there is a regular market for guineas at good prices, which are served as game at restaurants and hotels.

The common pearl guinea has darker flesh than the white variety. The white guinea is never found in its native country, the loss of color being an accident of domestication, which has been taken advantage of to breed a new variety. Wright leaves the inference in the minds of his readers that white guineas are hardly known in Europe, but in this country they are not uncommon. We have always thought they were not as wild as the darker colored ones, but this may be a mistake.

There is little difficulty in distinguishing the sexes to one who is familiar with these birds, but the beginner is often at a loss to tell the males from the females. The male has a coarser head than the female and a different voice. It is the female that has the characteristic cry of the breed. She alone calls "buckwheat, buckwheat," the male never using this call.

Good as a Watch Dog.

As night watches a few guineas are a perfect defense. They know a stranger at any time and will set up their clatter day or night, and he is a bold chicken thief who can withstand their discordant screeching when he invades a poultry house where guineas are kept.

Guineas should not be hatched until continuous warm weather has come, say, the last of May and during June. The female guinea usually does not sit until later than this. A small flock is profitable and interesting.—Poultry.

TURKEY TALK.

It is important that turkeys should have a wide range. The birds are natives of the wild forest and they have not fully been weaned from a desire to roam over a large section of country. In raising turkeys on the farm provision should be made to allow them to run at will all over the place. If you have alfalfa-fields for them to roam in, it will be all the better for both the alfalfa and the turkeys, for they will rid it of the grasshoppers and bugs that prey upon it. Wide range insures a variety of food and that is important in the production of poults. The birds will become sickly if fed only one kind of food, while they will make rapid growth if given a variety, notwithstanding the fact that the different feeds may contain practically the same food elements. Then a wide range, in a great measure prevents the increase of parasites. There is nothing that hinders the growth of the poults more than parasites, which increase very rapidly when the young turkeys are confined to small areas. In giving the birds a wide range, it should be remembered, however, that they cannot stand an excessive amount of dampness. They should not be given their liberty while there is a heavy dew on the ground or immediately after a rain.—Kansas Farmer.

Irrigation and Forestry

FOREST FIRES!

THE attention of all who inhabit or frequent the forested areas of California is called to this abstract of the forest laws:

Stat's. 1907: ch. 536, makes it a misdemeanor punishable by a fine of not less than twenty-five nor more than five hundred dollars to commit any of the following acts:

1. To set fire, or cause or procure fire to be set to any material being or growing on lands not the property of the person who sets such fire without the permission of the owner of the land, except that camp fires may be built on unclosed lands if the owner has not forbidden such building in any way and, provided the builder totally extinguishes the fire before leaving it.

2. To allow fires lawfully set to escape from the control of the person having charge of threof or to spread to the lands of another.

3. To build a fire anywhere (excepting camp fires, and fires set to facilitate redwod logging) during a dry season without first obtaining written permission from a fire warden.

4. To use any engine or boiler except such as use oil as fuel near any forest, brush or grass land unless such engines or boilers are provided with adequate devices to prevent the escape of fire from any part.

5. To refuse to obey the summons of any fire warden to aid in extinguishing fires. (Note: for this the fine it not less than ten dollars.)

Further information may be obobtained by addressing the State Forester, Sacramento, California.

DEAD EMPIRES.

Why do nations die? asks Forestry and Irrigation and then answers pointedly. Other causes may operate, but destruction of resources is fatal. Before the forests of Lebanon were destroyed Palestine supported in affluence ten million people. The mountains have long been denuded. Forbidding slopes, barren and ugly, rear their weird forms sharply above dismal and desolate valleys. Scarcely four hundred thousand people remain in all the region, and most of these are in wretched, hopeless poverty.

Syria, once maintaining a multitude of prosperous towns and cities —Antioch having a population of half a million—is at present the scene of irreparable ruin. The destruction of Syria's forests, begun 2650 B. C., followed by the disappearance of her soil and the decay of her industries, would alone have produced this effect. Babylon, once capital of the world, is a heap. Nineveth and Carthage, once the seats of mighty civilizations, and abundantly equipped by generous Nature for permanent life, are desolate wastes. Man destroyed the forests, and lands which once flowed with milk and honey were transformed into deserts.

FEARED THE PENALTY.

People—Come, come, Willie! Don't cry because you've barked your shin a little bit. Act like a man.

Willie (blubbering)—Yes! then you'd whip me. You told me you would if you ever caught me swearin'.

OVERFLOW LANDS.

It is possible a hint of value to owners of overflow lands along the Sacramento and San Joaquin rivers may be in the following item. Of course, those lands may be considered "too valuable," but standing timber will be valuable one of these days:

"President of the University of Illinois gave a lecture before the students there in which he discussed the uses and supply of timber and the utility of different kinds of trees. Dr. Burrill predicted disappointment in the results of the Illinois Central catalpa grove which has been planted to supply railroad ties, because it is planted on impervious clay land, while the suprisingly quick growths for which this tree is noted are made on rich soils. The lecturer pointed out that there are many rich lands that are useless for agriculture because of being frequently overflowed and remarked that these would be suitable sites for catalpa groves."

WHY NOT A "WOOD LOT."

Nearly every farm in the East has its wood lot. It is not there because of any foresight of the owner, as a rule, but its great value is being more and more brought to the mind of the owner. Now, why not a wood lot in many California ranches. About the only objection is that we can't plant today and gather tomorrow. But if even the older ones of this generation will plant trees in California soil and under California sun, it may prove a blessing—and a profitable one—to even the planter.

We now note that: "Forest planting studies for the benefit of farmers settling upon the lands irrigated by a number of the projects of the Reclamation Service, are being especially pressed by the government wherever such projects are nearing completion. In these regions trees are scarce or wholly wanting, and whatever forest growth is needed to provide protection for the farm or wood for farm uses must be secured artificially. Under such conditions the value of the forest stands out conspicuously. Wood and shelter must be had, and ground space must be given to forest trees, even on soil which in forested regions would be regarded as too good for any use but agricultural crops. Indeed, it is there most readily recognized that the forest itself is a true agricultural crop,

A NATIONAL RESOURCE.

Experience abroad and at home proves that national forests pay says Forestry and Irrigation. Our own, though in their infancy, yields more than half their annual cost; soon they will repay all of this cost and more. They are increasing in value fully ten per cent. per annum, while the cost of administering them is but one-third of one per cent., or one-thirtieth of their annual growth in value. This gain is in addition to the gain in general well-being from preserving forests, climate, scenery and the vast economic interests involved.

Our people are fearfully at sea on the forestry problem. Learn a lesson from France; there the government furnishes an army of 6000 men, foresters, rangers and keepers— a real army—subjected to military discipline, which, in war, is turned over from the Department of Agriculture to that of War. The government, in addition, furnishes all the seed to the land-owner. If under these and more favorable conditions the land-owner refuses to do the work, then the government steps in, pays for the land, and plants the trees.

The use of the waters for irrigating purposes of our great western rivers and their ten thousand tributaries in the mountain valleys has done more to stimulate the peopling of the West than anything since the great emigration from the East to the black prairies of the Middle West says the Farm and Home. It seems very strange under all these circumstances that Uncle Sam is finding so much trouble to secure settlers to come in and occupy the gracious acres brought into fruition by the reclamation service. If history could repeat itself this looks like a repetition of the banquet which the rich man spread and to which the invited guests did not come.

FOR INSTANCE.

Bridget (reading laboriously:) Hov you seen this, Pat? It sez here that whin a mon loses wan av his sinses, his other sinses gets more develyuped. F'r instans, a blind mon gets more sinse av hearin', an' touch, an'——

Pat Shure, an' it's quite thrue; Oi've noticed it meself. Whin a mon has wan leg shorter than the other, begorra, the other leg's longer, isn't it now?—[Exchange.

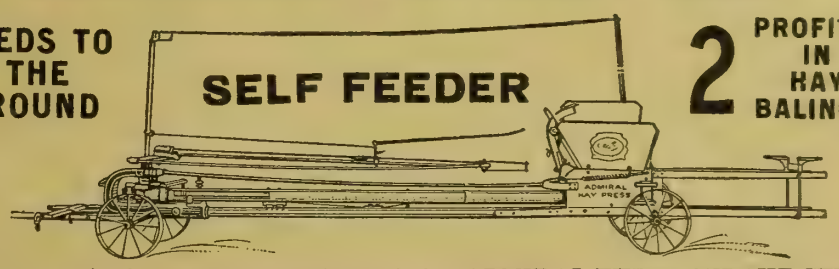
What is the oldest piece of furniture in the world? Answer—The multiplication table. What tree bears the most fruit to market? Answer—The axle-tree.

AN ADMIRAL WITHOUT COST

3 FEEDS TO THE ROUND

SELF FEEDER

2 PROFITS IN HAY BALING



The difference in the increased earnings of the ADMIRAL THREE-STROKE SELF-FEED PRESS more than pays for the press in one season, at a conservative estimate of 2½ tons per day over the old style two-beat, foot-feed press, besides the ease of labor on both men and team, and better work. Let us figure a little to convince you.

2½ Tons per day for one week, 15 tons at $1.50 net.....$ 22.50
One month's earnings over the other press (26 days)..... 97.50
On an estimate of five months' work out of the year..... ..... 487.50

The above gain with the ADMIRAL more than pays for the press.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.—Ed.

Flies on Stock.

What will keep flies from stock and from houses?—X., Pomona.

A cool, dark place should be provided for a horse or cow to run in to escape from the flies. Many washes are recommended, some manufactured and sold especially for the purpose which can be bought at feed stores and other places. A simple home made wash is: steep for some time one pound of tobacco stems to make when cool about three gallons. A little turpentine or if there be no sores a little coal oil may be added, say an ounce to the gallon. Wash the stock thoroughly and lice, flies and other pests will have but little use for such animals for a short time at least.

As to anything to burn in the house to keep flies away, any smoke is good but as hard on humans as on flies. Buhach is the best of anything we know of and when fresh and thoroughly dusted in a room or near a door, is very distasteful to all insects of which it will kill many.

Dr Oliver gives as a remedy for flies on stock to spray or sprinkle over the horse or cow a mixture of fish oil one quart and creoline 4 ounces.

Potato Troubles.

My potatoes were doing well till something affected them. The leaves turned black, dried up and the plant died. I noticed small green insects on the underside of the leaves which I called lice. The leaves curled over before they died.

Was it blight? Please discuss it, and give a receipt for Bordeaux mixture, if this is what to use.—Subscriber.

It is very likely that the lice on the under side of the leaves had something to do with them turning black and dying. The blight also affects potatoes that way. Bordeaux mixture will head off the blight if applied in time, but it will not affect the aphis (lice). These insects will disappear of their own accord as they have numerous enemies.

Spray the potatoes when they are a few inches high with Bordeaux mixture and again when eight or ten inches high. The mixture is made by mixing lime, bluestone and water in the proportion of 4—4—40 in the order named. Do not mix all together at once. Dissolve the bluestone in 20 gallons of water, slack the lime in plenty of water and make it up to 20 gallons and pour the two together so as to avoid a concentrated solution.

Planting Onions and Peanuts.

Is it too late to plant silver-skin onions, and a California variety of peanuts the first week in June?

Also is it too late to plant potatoes at this same time for a fall crop?—H. J. N.

I should deem it too late to plant silver-skin, at least for market. The same answer will apply to the peanuts. A more satisfactory and intelligent answer could be made if it was stated whether your correspondent wished merely to grow these for his own table, or for market. It is often possible to grow certain things on a small scale and with special attention, with a fair degree of success, when failure would surely result if undertaken on a large scale.

It is not too late to plant potatoes for the second crop. I have seen good results in this locality when planted as late as the third week in July, but should prefer from the first to the tenth. It is a good plan to be governed largely by the practices of one's own locality, for local conditions play such an important part in the operations of horticulture in California.—Q. A. L.

Dropping Figs.

An inquirer recently complained of his figs dropping before ripening and asked cause. The question was referred to Geo. C. Roeding of Fresno who has a wider knowledge of the fig than any other on the coast and he replies as follows:—

"It is quite probable that the fig tree, which your subscriber inquires about, is a Caprifig, or it may possibly be of the Smyrna type. Whether a Capri or Smyrna, either one would drop their figs, unless the Blastophaga was present. Kindly instruct your subscriber to send me a branch of his fig, about 12 inches long, also a few of the figs, wrapped up in a damp piece of burlap by mail, and possibly I can identify the variety for him.

Dodder.

Will you please tell me how to get rid of dodder in alfalfa?—Subscriber.

A common way to kill it when started in an alfalfa field, is to pile straw on it and burn it. This kills most of the alfalfa that is burned over. We one time cleaned it out of an alfalfa patch by cutting the alfalfa clean and as close to the ground as possible and then covered the stubble with moist dirt. This was done after all the dodder seed was sprouted. After covering with dirt we went over the spots and cut out with a pocket knife, every piece of stubble that came above the dirt. We worked on the theory that the succulent dodder would rot when covered with wet dirt. The dodder never showed up again and in due time the alfalfa come up uninjured. It will do no good to follow this plan after the dodder has gone to seed as covering it would only give it an advantage. Cover the dodder not less than three inches deep.

Garden Questions.

Shall I take up freesias and other bulbs when done blooming, or just leave in ground?

My hybrid perpetual roses have very long canes five to seven feet—should they be cut off now or in fall before watering—and how low down?

I got from a nursery a white flowered climber labelled Rhynchospermum—cannot find it anywhere—what is it?

Take up the freesias and store in cool, dry place. As to "other bulbs" that depends. Gladiolus, Ixia, Watsonias and many others should be taken up with their increase then, when placed back in the ground this fall will grow better in their enlarged space than if left together. Callas may be left in ground, but if old and crowded you will get better

flowers next season if they are taken up and divided. Amarillis, Agapanthus and others are injured by being disturbed.

The next issue of the Cultivator will have an article on July handling of bulbs in its ornamental garden department. Do not prune the roses until just before the fall watering. Then prune back severely and put on water and fertilizers.

Rhynchospermum is a comparatively new Japanese importation said to be a very nice plant. It is not a high climber.

Worms.

A green slug has taken possession of my young grape vines and is doing considerable damage by eating the young growth. Can you tell me how to get rid of them.—D. W. M.

Spray with one pound of Paris green to 200 gallons of water. Add about five pounds of lime to the wash.

Legal Queries

Weed Law.

Will you tell me if municipal trustees can enforce the present weed law in California? The marshall has threatened to cut the weeds on a vacant lot I own, and charge the same to me as a lien on the lot Can he do so?—R. P. S., Barkersfield.

Yes. The weed law is being enforced in different parts of the State and undoubtedly will be until declared void by the courts.

Lease.

Will you tell me if it is necessary for a lease to be acknowledged before a notary public? I leased a piece of ground for two years and nothing was said in the lease about the right to sell the property. Since the lease, the property has been sold and notice has been served on me that I cannot put in a crop on the land next year. The party who gave me the lease insists that I am a tenant at will because the lease was not acknowledged before a notary public and recorded. Is there anything in the contention of the original owner of the land, and what are my rights under the lease?—Subscriber, Corcoran.

Acknowledging a lease is for no other purpose than to have it recorded. An acknowledged and unrecorded lease for a term of more than one year is void as against any subsequent purchaser or mortgagee of the same property in good faith and for a valid consideration. This applies to all conveyances of real property. The Supreme Court of this State, however, has held that an unrecorded deed is valid as between the parties and as against subsequent purchasers having notice thereof, actual or constructive, at any time before the payment of money.

Homestead.

My husband filed a homestead in Nebraska. He worked the claim two years and died. Can I have the balance of the claim worked out and receive a patent from the government?—Sarah P. G., Redding.

Unless you have forfeited your rights by delay you are entitled to have the homestead proven up in your name. This will require a proper showing before the U. S. Land office in which he made his application and by complying with the homestead requirements; living on the homestead, etc.

Validity of Marriage Contracts.

I have been married to my present husband three years. He gave me a marriage contract to certain property he owned at that time. Since then it appears he had willed this property to his son and daughter. Am I cut out of my rights to the enforcement of my contract by this will? The will has been recorded.—W. H. M., Eureka.

It depends upon the contract. If you are now in possession of the property under the contract, the will will have no effect as to such property.

Mechanic's Lien.

I have been working under a subcontractor on a ditch, and I have not been paid my wages for two months. Can I file and enforce a mechanic's lien for my unpaid wages? What is allowed for the filing of a lien if such a lien can be filed?—R. M. P., Redlands.

If it is not too late you can file a lien. Better consult a local attorney.

Rights Without Will.

My husband died in Kansas without leaving a will. What is my dower right, and how can I secure it?—M. E. L., Alameda.

It depends upon whether he left any children or not. You have a half interest in his estate anyway, and may have it all. Probate proceedings in the proper court will be necessary to secure your interest. You may be able to secure your interest through local attorneys in this State.

Subject to Mortgage.

A buys land of B giving part cash and a note secured by mortgage for the balance. A sells this land to C giving him a deed in which a claim is inserted (subject to a mortgage which the party of the second part assumes and agrees to pay). C subsequently ascertains that the interest on mortgage and taxes have not been paid. Who will be required to pay this, A or C?—E. D. D.

C having assumed the payment of the mortgage will have to pay the interest thereon due. Otherwise the mortgagee will foreclose and sell his property. He will also have to pay the taxes or the land will be sold to the State for the payment of the same. He might recover the interest and taxes if his agreement was for the property to be clear of all encumbrances except the principal of the mortgage.

"CHEW AND CHOOSE."

The claims of Mr. Horace Fletcher and Professor Chittenden of Yale University, in regard to the effectiveness of thorough mastication of food in restoring perverted appetite to normal instincts, are corroborated by Professor Irving Fisher of Yale University in the report just issued describing one of a series of experiments he is conducting This report of Professor Fisher's shows that nine healthy Yale students who participated in the experiment doubled their working power physically and increased their mental capacity by strict attention to thorough mastication of food and obedience to the dictates of appetite. Under the chewing regime the appetite gradually called for less and less meat and other high-proteid foods.

The report of another experiment, which was with forty-nine flesh-eaters and flesh abstainers, has already been made public, and showed that those who either abstained from meat altogether or ate it sparingly had greater endurance than those who ate meat in the ordinary quantities.

Professor Fisher is an economist and not a physiologist, and is making these studies solely to get at the practical truth as to what the factors are which induce fatigue, for it is fatigue which sets the limit to the day's output of a man.

Professor Fisher is still engaged in his investigations, and other reports are to follow.

Household Department

O, SAW YE THE LASS?

O, saw ye the lass wi' the bonny blue een?
Her smile is the sweetest that ever was seen;
Her check like the rose is, but fresher, I ween;
She's the lovliest lassie that trips on the green.
The home of my love is below in the valley,
Where wild-flowers welcome the wandering bee;
But the sweetest of flowers in that spot that is seen
It the maid that I love wi' the bonny blue een.

When night overshadows her cot in the glen,
She'll steal out to meet her loved Donald again;
And when the moon shines on the valley so green,
I'll welcome the lass wi' the bonny blue een.
As the dove that has wandered away from his nest
Returns to the mate his fond heart loves the best,
I'll fly from the world's false and vanishing scene,
To my dear one, the lass wi' the bonny blue een.—Richard Ryan.

THE BLACKBALLING OF BARBARA BEALS.

HAVE you heard, Jennie, about the time that the P. Q. P. club blackballed Mrs. Beals?" said Mrs. Bliss of Allenville one afternoon last summer, to her sister, Mrs. Starks, who was visiting her.

"The P. O. P. club and Mrs. Beals! I didn't suppose there ever was a woman's club in this old town. But if there is, why shouldn't Mrs. Beals join in it? I think she is a charming woman."

Mrs Starks had lived in a city since her marriage, and the village happenings seemed quite provincial from her new viewpoint, though she much enjoyed her sister's stories, as she generally knew all the principals.

"Indeed, Jennie, Mrs. Beals is all you say, and more; and she is now one of the most popular women in Allenville, but she was not always so well liked, though I always say that jealously was at the bottom of it all in the first place."

Mrs. Bliss paused and critically examined the last spray she had made in her embroidery. Seeing her sister's look of expectant interest, she resumed:

"You see, when Clarence Beals returned from college and stepped into the old doctor's practice, of course he was the best catch in town, and all the matchmakers, young and old, set traps for him. He was courteous and attentive to all girls, but showed no preference for any one of them, thus keeping them all on tenterhooks, as it were.

"For even the few who disliked him were flattered by his attention. Matters were at the stage when Clarence left town quickly and was gone several weeks. When he returned he brought his bride. The surprise was complete. Instead of trying to make it pleasant for the stranger, very few called on her, except some of us younger married people, with no grown up daughters.

"After a few weeks Martha Arnold proposed that we make Mrs. Beals a member of our club. The club was simply a social organization, but as it was well known that members were pledged to pay no attention to malicious gossip, outsiders called us the Patterns of Propriety, or the P. O. P.'s.

"I noticed suppressed excitement all over the room as Marie mentioned Mrs. Beals, and many significant looks were exchanged while the votes were counted. When the result was announced, there were only two votes in favor of the newcomer.

"Instantly all pretence of order was forgotten, as each member tried to explain her reasons for voting as she had done. In the confusion I caught scraps of conversation, and just for fun I took notes as I listened.

"'She's no lady,' 'played the banjo keeper's daughter,' 'played the banjo in the saloon,' 'dances the mignonette in fancy costume,' were a few of the charges. I was thankful Mrs. Beals was not present.

"When the clatter had somewhat subsided Martha requested quiet while she addressed the meeting.

"You remember how she always talks, 'hits straight from the shoulder,' Jack says, and she certainly did this time. She told us how suprised she was that such gossip should be so credited among the members, then she explained her own part in starting it.

"'Mrs. Beals,' she said 'is an accomplished musician. I mentioned to several people that I understood she had played her banjo at a number of salons in her native city, also that she had mastered the mysteries of the minuet.

"'If my hearers had been better informed or consulted a dictionary, instead of jumping at such ridiculous conclusions, this blackballing would not have occured."

"As a parting shot she reminded us that every member present except herself and one other was subject to a fine, according to the rules of the club.

"Everybody looked rather foolish when Martha stopped talking, till someone moved that we vote again. Then Mrs. Beals was unanimously elected.

"Old Mrs. Jamison suggested that the fines should be collected at once and the money devoted to a supper in honor of Mrs. Beals.

"The supper was a success, but somehow the blackballing story leaked out and the club broke down soon after.

"I'm almost sure Mrs. Beals got an inkling of the facts, but she was just lovely and never acted as if she had heard a thing. We are going to make her president of our literary and musical society this winter."—Boston Post.

Mr. B. and Mrs. B., having returned from social gathering where something occurred which very much angered Mrs. B. Stormy words passed, and Mrs. B. proceeded to call Mr. B. all the mean names she could, and ended the conversation by adding that if there was any mean thing she had not mentioned, he was that also.

"If I had my way," growled old Tightfist, as he opened his morning mail at the breakfast table, "I'd have a sign placed on every letter box in town." "What kind of a sign?" queried his wife. "One reading, 'Post No Bills,'" answered the old man.

BUT ONCE.

We pass this way but once
The ripened harvest white
Has waited long
The reaper's song;
Thrust in thy sickle bright.
We pass this way but once!
There's work divine for thee;
On every hand
The needy stand
And sigh for sympathy.

STAND STRAIGHT.

Did you ever try the little mental science trick of walking along with an imaginary star upon your chest and an imaginary basket of eggs upon your head? I know of no better way to acquire perfect pose than this. Simply fancy that the star upon the center of your chest is a real, scintillating thing and you will find yourself carrying your shoulders like a military man bent upon exhibiting his gold buttons. They say that a desire to display his gold buttons, after all, has more to do with the West Point Cadet's perfect carriage than any other one thing.

When you are about to sit down remember that you still carry that basket of eggs upon your head, and you find yourself sinking gently and gracefully into your chair instead of just hunching into it. The same little bit of mental science will work wonders in the manner of climbing stairs. One cannot twist or bend or do any of the other hideous things women usually do upon a flight of stairs—with a basket of eggs upon her head.

THE PEST OF ANTS.

Both ants and cockroaches are the sworn enemies of the bedbug, and as such are to be encouraged. If their services can be dispensed with, however, they to should be made to fold their tents and silently steal away. For the red ant, cayenne pepper is a discourager of attentions. Where the foundations of a house are low and the pantry of easy access, the ants appear as by magic. Under these circumstances apply the pepper to the pantry shelves under the paper covers and scatter along the floor by the windows or crack where the ants made their entrance. Locate their hill, which will be near the foundation of the house, and pour boiling water or kerosene oil into the opening of each hole. This is the most heroic method. It is also stated that an abundance of cold water persistently applied with the hose to a lawn where ant hills abound will ultimately drive the ants away. A moist sponge dipped in sugar or molasses makes an excellent trap for ants. As soon as full drop in hot water. Black ants can often be driven away by sprinkling ashes saturated with kerosene about their haunts, and new leaves of green wormwood scattered about the house will also send them off in a hurry.

FOR COUGHS AND COLDS.

A few drops of camphor taken on sugar every three or four hours will usually check a cold. A little camphorated oil rubbed well into the chest when a cough is painful will give great relief.

As long as you are shielded from draft an open window is no source of danger even on the bitterest nights.

A cup of hot linseed tea taken before retiring for the night is a good remedy, and will often prevent a cold.

Hoarseness may be relieved by using the white of an egg, well beaten,

mixed with lemon juice and sugar. Take a teaspoonful every hour.

Cayenne pepper tea is good for a cold. Take a quarter of a teaspoonful of pepper and nearly a teacupful of water, and drink it as hot as can be swallowed.

For a tight, hoarse cough take hot water often, as hot as can be sipped. This will give immediate relief. A little lemon juice added to the water is beneficial.

Sneezing is averted by pressing the upper lip, because by doing so we deaden the impression made on a certain branch of the fifth nerve, sneezing being a reflex action excited by some slight impression on that nerve. Sneezing does not take place when the fifth nerve is paralyzed, even though the sense of smell is retained.

Squeeze a large, clean handkerchief out of water and place in a wad on the pillow of the patient, an inch or two from his nose, so that he can inhale the moisture. He will usually cease coughing in fifteen minutes. While this treatment may not cure a cough it will insure a good night's rest to many a sick child and tired mother.

To avoid taking cold keep the circulation in good condition by regular bathing and exercise. Be careful about clothing and do not make sudden changes in it unless there is a decided change in the weather. To change from a high to a low neck garment or from high shoes to low shoes always involves risk.

WITH THE COOK.

Macaroni and Cheese.

This combination of macaroni and cheese is, of course, very well known, but very often it is not palatably served. In the first place, have good macaroni, the small kind is best, and break into inch lengths, and this should be boiled in a large quantity of salted boiling water, until very tender, and it should be kept boiling all the time. When tender, drain, and pour cold water over it. The usual sauce served with it is white sauce, made by melting two tablespoons of butter, blending two of flour with it, half milk and half water. A layer of the boiled macaroni spread in a baking dish, then a layer of finely grated stale cream cheese, or Parmesan, with salt and pepper, then a layer of the sauce and so on till the dish is filled. A pleasant and appetizing change, is to use a tomato sauce instead of the white sauce. This sauce can be made of the canned tomatoes—acid is very delicious to serve not only with the above, but with boiled rice, and with meats of all kinds, as well as oysters, which are not ordinarily very good, are very good served with the tomato sauce.

Tomato Sauce.

One cup canned tomatoes (or fresh), ½ cup water, 1 teaspoon salt, 1 teaspoonful sugar, ½ teaspoon celery salt, 1-8 teaspoonful red pepper or paprica, 1 slice onion, 2 whole cloves, ½ bay leaf, 2 teaspoon flour, 2 teaspoon butter.

Boil all but the butter and flour together until tomatoes are soft, and press through sieve, then add to the blended butter and flour. A teaspoon of Worchestershire sauce improves it for a meat sauce. This amount will serve only about three persons.

Substitute for Hollandaise.

A good substitute for the usual Hollandaise sauce served with fish is as follows: 2 tablespoons butter, 2 tablespoons flour 1 1-4 cup water or soup stock, yolk of 2 eggs, 1½ tablespoon lemon juice, 2 tablespoons minced pickle. Blend butter and flour, add water, cook until thick, add beaten yolks of eggs, and then lemon juice and pickle.

Very nice croquettes may be made from any left over salmon and boiled rice, mixed with a stiff white sauce.

HOMELY HINTS.

Lemon juice and salt will remove iron rust.

A hot lemonade taken before going to bed will cure a cold on the lungs.

Gargle a bad sore throat with a strong solution of lemon juice and water.

A cloth saturated in lemon juice and bound about a cut or wound will stop its bleeding.

When you want eggs to come to a froth quickly have them almost ice cold before you break them.

Lemon juice mixed very thick with sugar will relieve that tickling cough that is so annoying.

The juice of half a lemon in a cup of black coffee without any sugar will cure sick headache.

A strong unsweetened lemonade taken before breakfast will prevent and cure a billious attack.

Lemon juice added to milk until it curds and these curds then bound upon parts swollen from rheumatism will bring relief.

Moth patches may be removed by a lotion of salicylic acid and rose water—two ounces of rose water to half a dram of acid.

To make a damp cupboard dry stand in it a bowl of quicklime, which must be occasionally renewed, as it loses its power.

When feeling faint or the symptoms of heart palpitation, bend the head downward. Some persons cannot stand so violent a remedy, but it is effectual, as it allows the blood to run to the head.

Do not attempt to clean suede gloves with gasoline. Draw them on the hands and scrub with a soft, old nail brush dipped in fuller's earth. Some cleaners combine equal parts of fuller's earth and powdered alum.

When ink is spilled on a carpet sop up as much as possible with blotting paper. Then wash the spot with a piece of rag dipped in milk, changing the milk when dirty. When the ink has disappeared wash the spot over with ammonia and water and no stain will be left.

"GONE GOOSE" MELODIES.

Rock-a-bye, Abey, on the tiptop,
While the wind's fair the boodle won't stop;
But when the gang breaks the boodle will fall,
And down will come Abey, boodle and all.

* * *

Ba, ba, black sheep,
Have you any pull?
Aye, sir; each confession
Will wash some dirty wool—
Some for us and some, perhaps,
For Mayor Schmitz as well,
But none for the little man
That lives in the hotel.

* * *

Abe and 'Gene stood in between
The Board and every grafter;
The Board broke down and told the town,
And they came tumbling after.—San Francisco Call.

"How did you get that black eye, Willie?'

"I got dot," replied Willie, disgustedly, "by waitin' to count ten when I was angry, like you told me to."

SIX HUNDRED FRUIT TRAYS FOR SALE cheap. Two by three; good condition. JOSEPH THORNDIKE, Pasadena, Cal.

Market men at San Francisco and Sacramento claim this is an exasperating season because of the fact that vegetables are so uncertain in supply. One day there may be a glut and the next the market entirely bare.

The Produce Markets

Los Angeles Markets

LOS ANGELES, June 26, 1907.—Trading in staple produce is about of the average and in fruits business was brisk. The greatest volume of transactions occured during the early hours of the morning so that by noon the fruit market was well cleaned up. The dairy market is rather weak owing to large supplies brought in by the high prices to which butter had been marked.

Butter.

The leading butter dealers of the city now admit that prices never should have advanced to 57½ cents this season. However, since the 57½-cent selling price was established they are anxious to keep prices at this level throughout the next two months, as a decline at the present will amount to no more than 2½ c, which has already been made by many dealers, and this reduction does not effect the price to the consumer as the retailer continues to sell at 60 and 70 cents per two-pound roll.

San Francisco hay merchants have petitioned the Southern Pacific asking the company to refuse to haul any new hay into that market until the old hay is gotten out of the way. Six thousand five hundred tons of last year's hay crop are still stored in the local warehouses. This room is badly needed for the storage of this season's crop.

E. J. Prien is investigating sugar beet conditions near Yolo.

Hay.

Alfalfa local	8.00@11.00
Oat	18@20
Wheat No. 1	21.50
Wheat, No. 2	13@17

Grain.

There is practically no change in trade conditions of the local wheat market. The millers are in the market for all the desirable grades of milling wheat obtainable and they are paying full quotations. Barley sells fairly well, but while prices are weaker and lower, the standard is still too high for any movement in the export trade.

Wheat, No 1	1.50@1.52½
Barley, No. 1	1.20@1.22½

Cocoanut cake, per ton	27.50@28.00

Citrus Market

LOS ANGELES, June 26, 1907.—Oranges are still insisting on a good finish for the season. Firmness prevails in practically all markets, with good demand for all better grades. Valencias are pressing their claims more each day and sweets and other budded fruits are being cleaned more and more out of the market.

Lemons are strictly favorites. The weather has been made to order and the boost so long waited for had the desired effect so that lemons are on the top shelf as to prices. The demand is keen at all markets.

Shipments.

Shipments to date aggregate 24,039 of which 2397 were lemons. Last year same date 23,554, of which 2906 were lemons.

NEW YORK, June 24.—The market is practically unchanged. Thirty-one carloads of oranges and one carload of lemons sold here today.

Commissioner Pease of San Bernardino County says that "several power sprayers are operating against the Florida red spider. They are using the sulphur-potash solution which has always proved satisfactory in this section."

A large dredger working near Folsom was wrecked in a peculiar way last week. In its work it dug into an old mining tunnel which took the water away from it, leaving it hopelessly stranded on dry ground.

The grape vines at the experiment station near this city are giving promise of an abundant yield this season, which reminds us that there is no country better adapted to the vineyard than that in this immediate vicinity.—Tulare Register.

The County Horticulture Commission of Yolo county held its first meeting this month. The pear blight was one of the principal points discussed, which developed from the discussion that apricot and almond crops will be especially light.

Mr. L. M. Landsborough of Florin, Sacramento County, is experimenting with two acres of tobacco.

Northern Sacramento valley sections almost invariably report good fruit crops.

Some magnificent wheat has been grown this season in the Moreno section east of Riverside.

COOL WATER WITHOUT ICE.

A picnic without Appell's South African water bag? Well, hardly, when once you have had one along, on a tramp or long trip of any kind.

Thousands of people are daily working or traveling where a good water supply is uncertain. The Appell South African water bag keeps water cool without ice, and as it is easily carried anywhere it is a most acceptable addition to the equipment of prospectors, surveyors, sportsmen, campers, miners, rangers, farmers, timbermen, threshing crews, millmen, railroad men, teamsters, boatmen, etc.

This Bag may be filled in the morning and will keep water refreshingly cool for fully forty-eight hours. It is strongly made, much lighter and less bulky than a jug or canteen. The popular size holds two and a half gallons and may be had from all hardware dealers. It is manufactured by the Adam Appell Company, of Portland, Oregon.
